SECTION 1

INTRODUCTION

1. INTRODUCTION

Weston Solutions, Inc. (WESTON®) has been retained by First Lawrence Financial, LLC on behalf of American Recycling of Massachusetts, Inc. (American), to perform a Phase II Comprehensive Site Assessment (CSA) for the former John C. Tombarello & Sons property ("the Site"), located in Lawrence, Massachusetts. Massachusetts Department of Environmental Protection (MDEP) has assigned multiple Release Tracking Numbers (RTNs) to this Site for elevated levels of oil and hazardous materials (OHM) detected in the soil; RTN 3-18126 is effective for this CSA. The Site is currently classified as a Tier 1C site under the Massachusetts Contingency Plan (MCP) - 310 CMR 40.0000.

This Phase II CSA Report has been prepared in accordance with the requirements of the MCP (310 CMR 40.0835), and includes the results of numerous field investigations and site inspections. Additional information pertinent to the Site has been obtained from the following documents previously submitted by Haley & Aldrich, Inc. (H&A):

- *Immediate Response Action (IRA) Completion Report* (May 2001)
- *Scope of Work Phase II Comprehensive Site Assessment* (April 2001)
- *Phase I Requirements/Tier Classification* (March 2000).

Because of the applicability of the Toxic Substances Control Act (TSCA) to response actions at this Site, this document has also been written to comply with the following requirements of 40 CFR 761.61 (a)(3):

> *At least 30 days prior to the date that the cleanup of a site begins, the person in charge of the cleanup or the owner of the property where the* [polychlorinated biphenyl] *PCB remediation waste is located shall notify, in writing, the* [U.S. Environmental Protection Agency] *EPA Regional Administrator, the Director of the State or Tribal environmental protection agency, and the Director of the county or local environmental protection agency where the cleanup will be conducted. The notice shall include:*
>
> (A) *The nature of the contamination, including kinds of materials contaminated.*

(B) *A summary of the procedures used to sample contaminated and adjacent areas and a table or cleanup site map showing PCB concentrations measured in all pre-cleanup characterization samples. The summary must include sample collection and analysis dates. The EPA Regional Administrator may require more detailed information including, but not limited to, additional characterization sampling or all sample identification numbers from all previous characterization activities at the cleanup site.*

(C) *The location and extent of the identified contaminated area, including topographic maps with sample collection sites cross referenced to the sample identification numbers in the data summary from paragraph (a)(3)(i)(B) of this section.*

(D) *A cleanup plan for the site, including schedule, disposal technology, and approach. This plan should contain options and contingencies to be used if unanticipated higher concentrations or wider distributions of PCB remediation waste are found or other obstacles force changes in the cleanup approach.*

(E) *A written certification, signed by the owner of the property where the cleanup site is located and the party conducting the cleanup, that all sampling plans, sample collection procedures, sample preparation procedures, extraction procedures, and instrumental/chemical analysis procedures used to assess or characterize the PCB contamination at the cleanup site, are on file at the location designated in the certificate, and are available for EPA inspection. Persons using alternate methods for chemical extraction and chemical analysis for site characterization must include in the certificate a statement that such a method will be used and that a comparison study which meets or exceeds the requirements of Subpart Q of this part, and for which records are on file, has been completed prior to verification sampling.*

SECTION 2

DISPOSAL SITE DESCRIPTION AND HISTORY
[30 CMR 40.0835(a)-(c)]

This document is intended to satisfy requirements (A), (B), and (C) above, as well as the requirements for an MCP Phase II CSA. A Remedial Action Plan, which has been submitted with this report, and a Remedy Implementation Plan, which will be submitted under separate cover, will satisfy requirements (D) and (E) above. Both of these reports will also be prepared in accordance with the MCP; specifically, 310 CMR 40.0850 and 40.0870, respectively.

2. DISPOSAL SITE DESCRIPTION AND HISTORY [30 CMR 40.0835(a)-(c)]

As previously stated, the disposal site presented in this CSA is the former John C. Tombarello & Sons scrap metal recycling property located at 207 Marston Street in Lawrence, Massachusetts. As shown on the 7.5-minute United States Geological Survey (USGS) Quadrangle Site Locus Map (Figure 2-1), the Site is bounded by Marston Street to the west, Hofmann Avenue to the north, Route 495 to the east, and the Sons of Italy Lodge, a soccer field and a high school to the south. The Merrimack River is located approximately 400 feet (ft) east of the property boundary.

The Site footprint comprises 14 acres. The northern portion of the Site was formerly used for metals recycling, while the southern portion was formerly used first for soap manufacturing, and then as a community landfill by the City of Lawrence. A paper recycling transfer station is currently operated on a 5-acre parcel to the southwest of the Site. The property is occupied by several buildings including: a 3,000 square foot (ft^2) office/scale house; a 3,000 ft^2 single family dwelling; a 24,000 ft^2 metal shop/garage; a 11,000 ft^2 furnace building; a 750 ft^2 press/baler building; and two shear buildings (2,500 ft^2 and a 6,500 ft^2, respectively). Numerous sheds and outbuildings are also located on the Site. Other site features include a soil berm adjacent to Route 495, overhead and subsurface utilities (telephone, electric, storm drains, and gas and water lines), and a sanitary sewer easement that bisects the Site from east to west. Reportedly, the soil berms were constructed from shallow site soils in conjunction with earthwork for Route 495. In addition, soil materials intermixed with metal are stockpiled adjacent the berms. These, and all pertinent site features, are shown on the Site Map (Figure 2-2).

In 1998, the John C. Tombarello & Sons metals recycling facility closed, and American bought the property. In association with the sale of the property, an environmental site assessment was conducted by W.Z. Baumgartner and Associates, Inc. (WZB). Results of the site assessment indicated that concentrations of OHM exceeding MCP Reportable Conditions existed at the Site. Consequently on 31 March 1999, MDEP assigned RTN 3-18126 to the Site and issued a *Notice of Responsibility* (*NOR*) and *Interim Deadline Letter* to both the former and new site

owners. As a result of the *NOR*, both Tombarello Recycling, Inc. (Tombarello) and American were required to submit an IRA Plan and Imminent Hazard (IH) evaluation to further assess the environmental conditions at the Site. The IRA Plan was filed on 21 April 1999, by Higgins Environmental Associates, Inc. (HEA) on behalf of Tombarello and American. The IRA Plan included removal of a soil stockpile contaminated with heat transfer oil (RTN 3-16817), collection and analysis of surficial soil samples, and sampling and analysis of existing groundwater monitoring wells for the IH evaluation. The IH conditions were addressed through erection of a barbed-wire perimeter fence to eliminate site access by non-authorized personnel.

On 21 June 1999, MDEP issued another *NOR* for the Site and assigned RTN 3-18431 for oily sludge that was observed on the baler/press room floor. American contested that the sludge originated from the sewer and consequently, RTN 3-18431 was retracted pending further evaluation of the sewer as a potential migration pathway.

In April 2000, MDEP linked RTN 3-18431 with RTN 3-18126, and the property has been subsequently classified a Tier 1C Site under the MCP (310 CMR 40.0000). The Site is intended for future capping and redevelopment as a light-industrial property. A list of major reports and select relevant legal correspondences regarding the Site and associated activities at the Site is included in Appendix A.

SECTION 3

DISPOSAL SITE HYDROGEOLOGICAL CHARACTERISTICS
[30 CMR 40.0835(d)]

3. DISPOSAL SITE HYDROGEOLOGICAL CHARACTERISTICS [30 CMR 40.0835(d)]

The surficial geology of the Site has been mapped as artificial fill overlying river terrace and flood plain deposits consisting primarily of well-sorted fine sands and silts (USGS Surficial Geology Map for the Lawrence Quadrangle, 1951-1952). Bedrock outcrops were not mapped within the vicinity of the Site. Soil test borings completed by HEA in 1999 verified that site soils are comprised of very fine brown sands with minimal silt and gravel content. Test boring logs prepared by HEA are included in Appendix B.

Depth to groundwater at the Site was determined by HEA to range from approximately 5 to 11 ft below ground surface (bgs), and groundwater flows in an easterly direction towards the Merrimack River. The MDEP MASS GIS Site Scoring Map dated 29 March 2000 (refer to Figure 3-1), indicates that approximately one half the property (mainly the eastern portion) overlies a medium yield aquifer. This aquifer has been identified as a Non-Potential Drinking Water Source Area (NPDWSA).

SECTION 4

NATURE AND EXTENT OF CONTAMINATION
[30 CMR 40.0835(f)]

4. NATURE AND EXTENT OF CONTAMINATION [30 CMR 40.0835(f)]

The Site has undergone several phases of investigation and assessment since its closure in 1998. The nature and extent of contamination is based on both historic and WESTON sampling and analytical results acquired in support of these investigations/assessments. In July 1998, Sprague Energy excavated soils contaminated with heat transfer oil (RTN 3-16817). In August 1998, WZB conducted a Phase I Site Assessment, which included: researching the history of the Site and surrounding area; collection and analysis of surface and subsurface soil samples; and installation and sampling of groundwater monitoring wells. In 1999, HEA conducted the IRA previously described in Section 2. In 2003, WESTON was retained by First Lawrence Financial, LLC to conduct additional site characterization activities to delineate the nature and extent of contamination (specifically PCBs in soil, groundwater, and river sediment) at the Site. This included sampling and analysis of surface and subsurface soil, groundwater, catch basin sediment, outfall sediment, and river sediment. A summary and discussion of sample results obtained during the investigations and assessments described above is presented in the following subsections.

4.1 SAMPLE COLLECTION PROCEDURES AND ANALYTICAL METHODS

4.1.1 Historic data

Prior to performance of the nature and extent of contamination at the Site, WESTON conducted a review of sample data collection and analysis procedures with respect to currently approved practices. The following historic data were evaluated:

- Soil:

  1998 - WZB (Table 1, Appendix C)
  1999 - HEA (Table 2, Appendix C)
  2001 - H&A (Table 3, Appendix C)

- Groundwater (Table 7, Appendix C):

  1998 - WZB
  1999 – HEA

- Sediment (Table 8, Appendix C):

  2001 – H&A

WZB Data

The WZB data, which are the oldest data used, were evaluated via review of the WZB Phase 1 *Environmental Site Assessment* (WZB, 1998). Appendix G of the WZB report provides groundwater sampling summary sheets indicating well depths, elevations, purging methods and purge times, pumping volumes, and field measurements of temperature, conductivity, pH, and turbidity. In addition remarks on the general appearance, odor, and other physical characteristics of note pertaining to the groundwater are included. The summary sheets indicate the wells were purged via submersible pump. No unusual circumstances or breach of accepted protocols were indicated on the sheets, which would compromise the accuracy or integrity of the data. It is unclear from the summary sheets whether low flow sampling methods were used.

In addition, Appendix G of the WZB document provides boring logs and well completion information for the wells installed and sampled, as well as elevation information for select samples. Laboratory data packages were not supplied with the WZB report. Rather, tabulated data indicating detection limits for each sample were provided, along with some limited Chain-of-Custody information. Neither Appendix G. nor Section 9 (Intrusive Investigation) of the report indicated analytical methods used or sampling procedures adhered to. However, Subsection 2.3 – Limitations and Exceptions to Investigation – indicates that the site investigation was conducted in full compliance with Standard *Practice for Environmental Site Assessments: Phase 1 Environmental Site Assessment Process* (ASTM E-1527). Therefore, the data were deemed acceptable for inclusion in this Phase II CSA, and to form part of the basis for future response action decisions at the Site.

HEA Data

Details of HEA data collection and analysis sample collection and analytical methods were not included in their *Modified Immediate Response Action (IRA) Plan* (HEA, June 1999). However, the results of their work and a brief description of sampling methods and laboratory analytical procedures were provided in the Final IRA Completion Report submitted by Haley and Aldrich, Inc. (H&A, 15 May 2001). The following paragraphs present the description, as included in the IRA Completion Report:

> *HEA collected discrete surficial soil samples on a grid pattern on 26 April 1999. Focused collection of surficial soil samples was conducted at previous soil sampling locations and at ten-foot distances to the north, south, east and west of previous sampling locations.*
>
> *A total of forty-five discrete grid samples of soil were collected from depths of zero to six inches as outlined in the Modified IRA Plan dated 1 June 1999 prepared by HEA.* [Photoionization detector] *PID headspace screening for* [volatile organic compounds] *[VOCs was conducted on all samples and results were all less than 0.5 parts per million.*
>
> *HEA collected an additional nineteen discrete soil samples for laboratory analysis on 28 April 1999. The sampling locations were determined based on visual classification of soil and previous sampling locations where potential Imminent Hazard Conditions might be present.*
>
> *Laboratory analysis included the following:*
>
> - *Polychlorinated biphenyls (PCBs) by U.S. EPA Method 8082;*
> - [Extractable Petroleum Hydrocarbons] *EPHs by MA DEP-specified methods;*
> - *Lead and cadmium by U.S. EPA Method 6010;*

- *Volatile organic compounds by U.S. EPA Method 8021B (Halogenated) and U.S. EPA Method 5035; and*
- *Volatile petroleum hydrocarbons by MA DEP-specified methods.*

All soil samples were analyzed for PCBs, lead and cadmium. The remaining parameters were analyzed for select samples chosen by HEA based on previous laboratory results from the Site.

An additional five surficial soil samples were collected by HEA on 2 June 1999 as planned in the Modified IRA Plan dated 1 June 1999 prepared by HEA and outlined in the IRA Status Report dated 28 July 1999 prepared by HEA. The samples were collected in the proximate location of the previous sample location SB6-SS1. One sample (SB6-SS2) was collected at the same location as SB6-SS 1 and four additional samples were collected at a distance of ten feet to the north, south, east, and west of SB6-SS1.

Four groundwater monitoring wells (MW-1, MW-2, MW-3, and MW-4) were to be re-sampled based on laboratory results of groundwater sampling documented in the *Environmental Site Assessment Report* dated August 1998 prepared by Baumgartner & Associates, Inc. During a site inspection conducted on 23 May 1999, only one well (MW-l) was located and developed. Three additional monitoring wells (MW-5, MW-6, and MW-7) were installed 2 June 1999 in approximate locations of the previously existing wells. (*Note:* Monitoring well installation logs were provided in Appendix C of the IRA Completion Report).

The three new wells were developed 3 June 1999. Groundwater sampling was conducted 10 June 1999 by HEA using low flow sampling techniques. Samples from each well were analyzed for VOCs by EPA Method 8260B.

H&A Data

Laboratory data packages for the 35 soil samples collected by H&A in 2001 are presented in Appendix C. Soil samples were analyzed for PCBs via EPA Method 8082. However, due to contractual issues between H&A and American Recycling, formal, tabulated sediment data and laboratory packages were not provided by H&A to WESTON. Rather, the data were transmitted

by H&A via telephone and placed on a map in locations previously designated by H&A. It is assumed based on knowledge of H&A procedures and historical familiarity with their previous work that sample collection and analytical procedures were rigorous enough to ensure the level of data quality required by Comprehensive Environmental Response, Compensation, and Liability Act and the MCP.

4.1.2 WESTON Data

4.1.2.1 Data Collection Handling, and Shipment Procedures

12 and 13 February 2003

Under WESTON supervision, ADH of Fitchburg, Massachusetts advanced 13 soil borings to a depth of 7 ft. Each boring was advanced, by a track-mounted GeoProbe unit with direct-push technology and 4-foot dedicated lexane sleeves. At each soil boring location, a WESTON geologist collected soil samples from discreet intervals between 0 and 7 ft bgs based on visual and olfactory observations. The samples were screened in the field using an organic vapor monitor (OVM) equipped with a PID. All volatile samples were collected directly from the lexane sleeves as to minimize soil disturbance. The remaining volume of soil from the sampled interval was transferred to a dedicated aluminum mixing vessel. After homogenization was completed, the sample was transferred to the appropriate sample containers and immediately placed on ice. Under chain-of-custody procedures the soil samples were submitted via courier to ESS Laboratory, Inc. in Cranston, Rhode Island. The samples were analyzed EPH (Commonwealth of Massachusetts method), volatile petroleum hydrocarbons (VPH) (Commonwealth of Massachusetts method), Resource Conservation and Recovery Act (RCRA)-8 metals (EPA Methods 6010A and 7471A), and PCBs (EPA SW-846 Method 8082). Upon completion, each boring was backfilled to the surface with a combination of soil cuttings and clean filter sand.

Upon completion of the soil boring program, four locations were completed as microwells. At four of the locations, the borings were continued to a depth of approximately 16 ft bgs and the wells were constructed with ten feet of 1.25-inch diameter, 10-slot polyvinyl chloride (PVC) well screen and 6 ft of flush-jointed PVC riser. The annular space around the well material was

backfilled with clean filter sand to a depth of 4 ft bgs and a 2-foot thick bentonite seal was installed above the sand pack. The wellhead was completed at the surface with a 4-inch-diameter, flush-mounted steel road box set in concrete.

Following installation of the microwells, ADH developed the wells by purging water from them with a peristaltic pump and dedicated polyethylene tubing. Once the purge water was free of silt and sand to the unaided eye, a WESTON geologist collected groundwater samples from each well directly into pre-preserved sample containers and immediately placed them on ice. Following chain of custody procedures, the samples were submitted to ESS Laboratory in Cranston, Rhode Island for analysis of VOCs and dissolved RCRA-8 metals, by EPA Methods 8260B, and 6010A and 7471A, respectively. The dissolved metals samples were field filtered into a pre-preserved sample container using a 0.45 micron in-line filter.

WESTON personnel collected three sediment samples, from the Merrimack River, which flows past the Site. The sediment samples were collected using a stainless steel bucket auger, which was decontaminated with alconox and water wash and a deionized water rinse in between each sample collection. The sediment was transferred from the auger to stainless steel mixing bowls and homogenized with a dedicated stainless steel scoop. The samples were screened in the field using an OVM equipped with a PID. The homogenized sediment was transferred from the bowls to the appropriate sample containers and placed on ice. Following chain-of-custody procedures, the samples were couriered to ESS Laboratory in Cranston, Rhode Island. The sediment samples were analyzed for EPH (Commonwealth of Massachusetts Method), PCBs (EPA SW-846 Method 8082), RCRA-8 metals (EPA Methods 6010A and 7471A), and total organic carbon (TOC) (Method 415.1 or 9060).

14 and 15 July 2003

Under WESTON supervision, ADH of Fitchburg, Massachusetts advanced 22 soil borings to a depth of 4 ft bgs. The soil borings were laid out over the 14-acre property with 100-ft by 100-ft grid spacing. At each boring location a soil sample was collected from depth intervals of 0–0.5 ft bgs and 1–3 ft bgs. Samples from two adjacent grids were then composited into one sample for each depth interval. A more detailed description of direct-push and soil sampling methodology is described in the paragraphs above, which detail sampling and analysis activities

for 12 and 13 February 2003. Following collection, the samples were packed in ice and under chain-of-custody procedures were submitted via courier to Resource Laboratory, Inc. in Portsmouth, New Hampshire. The soil samples were analyzed for total PCBs by EPA Method 8082 using Soxhlet (Method 3540) extraction and acid/florisil cleanup.

In addition, WESTON personnel also collected discrete samples from two previously identified PCB "hot spots": WSB-6 (WESTON, February 2003) and SB-6 (HEA, June 1999). Samples were collected at depth intervals of 0-6 inches, 1-2 ft, and 2–3 ft bgs. A second round of samples was collected at the same depth intervals at locations that were a distance of 10 ft north, south, east, and west from each "hot spot". A total of 33 discrete samples were analyzed from 11 sample locations surrounding the two "hot spots". A more detailed description of direct-push and soil sampling methodology is described above in the paragraphs above, which detail sampling and analysis activities for 12 and 13 February 2003. Following collection, the samples were packed in ice and under chain-of-custody procedures were submitted via courier to Resource Laboratory, Inc. in Portsmouth, New Hampshire. The soil samples were analyzed for total PCBs by EPA Method 8082 using Soxhlet extraction and acid/florisil instrument decontamination procedures.

2 September 2003

In September 2003 under WESTON supervision, ADH advanced 47 soil borings from the five composite sample locations where elevated concentrations of PCBs were detected in July 2003. All procedures and methodology implemented for soil sample collection of the "hot spots" during the July 2003 sampling effort are described above in the section detailing characterization activities occurring on 14 and 15 July 2003. Following collection, the samples were packed in ice and under chain-of-custody procedures were submitted via courier to Resource Laboratory, Inc. in Portsmouth, New Hampshire. The soil samples were analyzed for total PCBs by EPA Method 8082 using Soxhlet extraction and acid/florisil instrument decontamination procedures.

4.1.2.2 Laboratory Quality Assurance/Quality Control and Data Validation

Volatile organic compounds, semi-volatile organic compounds (SVOCs), total metals, PCBs, EPH, and TOC data generated for the Tombarello Site project by the off-site laboratories, ESS of Cranston Rhode Island, and Resource Laboratories, Inc. of Portsmouth, New Hampshire (performed PCB analysis only) were analyzed by EPA SW-846 Methods and EPA Methods for Chemical Analysis of Water and Wastes per 40 CFR 136. Data was reviewed in accordance with the *U.S. EPA New England Region I Data Validation Functional Guidelines for Evaluating Environmental Analyses* (EPA, December 1996). The following QC indicators were reviewed; holding times, sample preparation, method blanks, surrogate recoveries, matrix spike recoveries, field duplicate results, laboratory control spike (LCS) recoveries, and laboratory duplicates (metals only) A modified Tier II data review utilizing a Data Review Checklist was performed.

In some instances, matrix spike recoveries did not meet quality control (QC) criteria stated in the laboratory QC plan or standard operating procedure. No qualifications were added to data results if these compounds met recovery limits in the LCS sample. In the February 2003 ESS data package, several surrogates in the EPH and PCB analyses could not be quantitated due to matrix interferences or high dilutions. Blank spike and LCS spike results were within QC limits; therefore, data quality was not compromised. Field duplicate samples were analyzed at a rate of one per ten and results were acceptable. As stated in the 12 April memo, the laboratory was unaware of the need for presumptive certainty for the September 2003 data deliverable; therefore, some QC requirements were not met. However, none of the discrepancies noted neither in that April memo, nor in the previous review of the analytical results would cause the quality of data to be compromised.

4.2 ANALYTICAL RESULTS

The following analytical data have been used to assess the nature and extent of contamination at the Site:

- Soil:

  1998 - WZB (Table 1, Appendix C)
  1999 - HEA (Table 2, Appendix C)

2001 - H&A (Table 3, Appendix C)
2003 - WESTON (Table 4, 5, and 6, Appendix C)

- Groundwater (Table 7, Appendix C):

  1998 - WZB
  1999 – HEA
  2003 - WESTON

- Sediment (Table 8, Appendix C):

  2001 – H&A
  2003 – WESTON

All soil sample locations are shown on Figure 4-1, groundwater sample locations are shown on Figure 4-2, and raw laboratory data packages are provided in Appendix D. Sample procedures, results, and action levels are summarized in Subsections 4.2.1 through 4.2.3, and discussed in detail in the following documents:

- 8 August 2003: WESTON letter to the EPA (Ms. Kimberly Tisa)
- 15 May 2001: *IRA Completion Report* (H&A)
- 1 June 1999: *Modified IRA Plan* (HEA)
- August 1998: *Environmental Site Assessment* (WZB)

As indicated above, all WESTON data have undergone EPA Tier II validation. Historic data collected by subcontractors other than WESTON have not been validated; however, these data have been checked for quality and reasonableness, and have been found of sufficient quality to support comprehensive response actions under the MCP. The following should also be noted with regards to available site data:

- Raw laboratory data packages for samples collected by H&A in Year 2001 were not made available to WESTON due to contractual difficulties between H&A and American. The H&A data, which are presented in tabular format only (Tables 3 and 7, Appendix C), were collected recently enough and show good comparability to other data collected for the Site, to be deemed acceptable for use as historic data in support of CSA activities.

- Data collected by WESTON in September 2003 were not analyzed in strict accordance with the newly promulgated Data Enhancement/Presumptive Certainty requirements for data collection/analysis under the MCP (i.e., no presumptive certainty checklist was provided by the laboratory). However, as allowed for under the MCP, data review and validation have resulted in the determination that the data are of sufficient quality to support comprehensive response actions and decisions

under the MCP. A chemist's memorandum documenting this determination is provided in Appendix E.

4.2.1 Soil

In July 1998, WZB collected 15 soil samples between 0-11 ft bgs from nine soil boring locations. The samples were analyzed for SVOCs, metals, VOCs, PCBs, and total petroleum hydrocarbon (TPH). As shown in Table 1 (Appendix C), results indicated exceedances above the MCP Reportable Concentration Standard (RCS-1) criteria for the following analytes: SVOCs (Benzo(a)Anthracene, Benzo(a)Pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Chrysene, Indeno(1,2,3-cd)Pyrene, 2-Methylnaphthalene, Naphthalene, and Phenanthrene); TPH (diesel range); PCBs (Aroclor 1221, Aroclor 1260, and Aroclor 1248); and metals (lead).

On 26 April 1999, HEA collected a total of 45 discreet soil samples from depths of 0-6 inches at previous WZB sample locations and at 10-ft distances to the north, south, east and west of those locations (sample results are not included in this Phase II CSA Report). The samples were analyzed for the following analytes using the laboratory methods indicated:

- **PCBs:** EPA Method 8082
- **EPHs:** MDEP-specified methods
- **Lead and Cadmium:** EPA Method 6010
- **VOCs:** EPA Method 8021B (halogenated) and EPA Method 5035
- **VPH**: MDEP-specified methods

Based on the results of the 26 April 1999 sampling event [refer to the *Modified IRA Plan* (H&A, 1999)], HEA collected an additional 19 discreet soil samples on 28 April 1999, to better define locations where potential IH conditions might be present. These locations included: SB-5; SB-6; SB-7; and SB-8. The samples were analyzed for the analytes listed above using the laboratory methods indicated. Sample results, which are presented in Table 2 (Appendix C), identified exceedances above the MCP RCS-1 criteria for the following analytes: EPHs (C9-C18 aliphatics, C19-C36 aliphatics, C11-C22 aromatics, Benzo(a)Anthracene, Benzo(a)Pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Chrysene, and Indeno(1,2,3-cd)Pyrene); metals (lead); VOCs (methyl tertiary butyl ether, Trichlorofluoromethane); and PCBs (Aroclor 1254 and Aroclor 1260). Detection of Aroclor 1260 at a concentration of 57 milligrams per kilogram (mg/kg) at sample location SB6-SS1 resulted in identifying this location as a potential IH.

To further delineate the potential IH condition, HEA collected an additional five discrete soil samples on 2 June 1999, in the proximate location of the previous SB6-SS1 sample. One sample (SB6-SS2) was collected at the same location as SB6-SS1 and four additional samples were collected at a distance of 10 ft to the north, south, east, and west of this location. The samples were analyzed for the same analytes using the same laboratory methods as previously described for the April 1999 sampling events. The sample results, which are presented in Table 2 (Appendix C), showed an elevated concentration of Aroclor 1260 (92 mg/kg) detectable at sample location SB6-N1.

In September 2001, H&A collected 35 soil samples between 0-15 ft bgs for laboratory analysis. Twelve of these samples were collected from the soil berm and three were collected from the vicinity of the Baler Press Building (refer to figure 4-1). The samples were analyzed for PCBs only using EPA Method 8082. Sample results indicated exceedances above the MCP RCS-1 criteria of 2 mg/kg for the following PCBs: Aroclor 1016 (average = 4.9 mg/kg; max = 11 mg/kg); Aroclor 1242 (average = 65 mg/kg; max = 66 mg/kg); Aroclor 1254 (average = 5.4 mg/kg; max = 11 mg/kg); and Aroclor 1260 (average = 16.9 mg/kg; 78 mg/kg).

In February 2003, WESTON collected 28 soil samples between 0-7 ft bgs from 13 boring locations (refer to Figure 4-1). The samples were analyzed for EPH, metals, and total PCBs. Sample results indicated exceedances above the RCS-1 criteria for all analytes tested, with the exception of selenium and silver. A total of 12 samples had detectable PCB concentrations greater than the RCS-1 criteria of 2 parts per million (ppm), but less than the site-specific criteria of 75 ppm. Only one sample, which was collected at WSB-6 between 0-1 ft bgs, exceeded 75 ppm. The February 2003 sample results are presented in Table 4, Appendix C.

Additional site characterization sampling was conducted by WESTON in July 2003 to further delineate previously identified PCB-contaminated areas. Samples were collected from the center of each 100-ft by 100-ft grid (refer to Figure 4-1) at depth intervals of 0–1 ft bgs and 1–3 ft bgs. Samples from two adjacent grids were then composited into one sample for each depth interval. All samples were analyzed for total PCBs by EPA Method 8082 using Soxhlet extraction and acid/florisil instrument decontamination procedures. A total of 44 composite samples (22 samples from 0-6 inches, and 22 samples from 6-12 inches) were analyzed for total PCBs. The analytical results, which are presented in Table 5 (Appendix C), indicated the presence of

PCBs at concentrations of 37.5 ppm or greater at 5 of the 22 boring locations where samples were analyzed. These locations included: CD-35; DE-13; FG-13; FG-35; and JK-46. A threshold of 37.5 ppm was used to evaluate the data because when multiplied by a factor of two to account for the number of grab samples per composite sample, it equals EPA's recommended site-specific action limit of 75 ppm. The concentration of PCBs detected at these five locations ranged from 37.8 ppm in composite sample JK-46 to 200 ppm in composite sample CD-35. At four of the five locations, the vertical extent of PCB contamination was delineated by the sample collected from the interval below it, where the concentration was less than 37.5 ppm. At the fifth location (CD-35), the elevated concentration was detected in the 1 to 3-ft interval; however, in accordance with WESTON's proposed sampling plan, no samples were collected beyond a depth of 3 ft bgs.

During the July 2003 sampling event, WESTON also collected discrete samples from two previously identified PCB "hot spots": WSB-6 (WESTON, February 2003) and SB-6 (HEA, June 1999). Samples were collected at depth intervals of 0-6 inches, 1-2 ft, and 2–3 ft bgs. A second round of samples was collected at the same depth intervals at locations that were a distance of 10 ft north, south, east, and west from each "hot spot". A total of 33 discrete samples were analyzed from 11 sample locations surrounding the two "hot spots" (refer to Figure 4-1). Sample results indicated PCB concentrations in exceedance of the 75 ppm action level in two samples around the former "hot spot" WSB-6: WSB-26 at 510 ppm (1-2 ft bgs) and WSB-31 at 13,000 ppm (0-1 ft bgs). Boring WSB-26 was advanced immediately next to former boring location WSB-6 to confirm the concentration of PCBs (2,700 ppm) previously detected during the February 2003 sampling event. Boring WSB-31 was advanced 10 ft to the east of boring location WSB-6/WSB-26. Due to the elevated level of PCBs detected at this location, WESTON instructed the laboratory to also analyze samples collected at WSB-32, which was located an additional 10 ft to the east of WSB-31. The analytical results of the samples collected at WSB-32 indicated no detections of PCBs above 75 ppm; therefore, it was concluded that the horizontal extent of PCB contamination at sample location WSB-31 had been delineated. There were also no detections of PCBs at depths greater than 1-2 ft bgs and 0-1 ft bgs at sample locations WSB-26 and WSB-31, respectively; therefore, it was concluded that the vertical extent of PCB contamination had also been delineated in this area.

There were no detections of PCBs above the site-specific criteria of 75 ppm in any samples collected at or around former "hot spot" location SB-6; therefore, it was concluded that PCB levels in soils within this area were sufficiently delineated.

Although both "hot spot" locations were satisfactorily delineated by the 75 ppm site-specific criteria, a total of 15 sample results indicated elevated levels of PCBs above the 2 ppm MCP RCS-1 criteria within the vicinity of both "hot spot" sample locations. Sample results for the July 2003 sampling event are presented in Table 5, Appendix C.

In September 2003, WESTON collected a total of 44 discrete soil samples from the five composite sample locations where concentrations of PCBs were detected in July 2003 above the 75 ppm site-specific criteria (refer to Table 5, Appendix C). The September 2003 samples were collected from ten boring locations that comprised the five composite samples. These locations included borings DE-12, DE-23, CD-34, CD-45, FG-12, FG-23, FG-34, FG-45, JK-45, and JK-56. Refer to Figure 4-1 for sample locations. With the exception of locations CD-34 and CD-45, the proposed sampling intervals for the borings was the same as those collected from the two "hot spot" locations during the July 2003 investigation (i.e., 0-6 inches bgs, 1-2 ft bgs, and 2-3 ft bgs). At boring locations CD-34 and CD-45, samples were also collected at a depth interval of 3-4 ft bgs. Samples were analyzed for total PCBs only using EPA Method 8082 with Soxhlet extraction and acid/florisil instrument decontamination procedures. Sample results, which are presented in Table 6 (Appendix C) showed detectable concentrations of PCBs above the 75 ppm action level in four samples: WSB-76 (1-2 ft bgs); WSB-77 (2-3 ft bgs); WSB-78 (1-2 ft bgs); and WSB-79 (1-2 ft bgs). Additional samples collected at greater depths resulted in vertical delineation of the PCB concentrations to levels less than 75 ppm as follows:

- WSB-76 = 0.7 ppm (2-3 ft bgs)
- WSB-77 = 8.4 ppm (3-4 ft bgs)
- WSB-78 = 14 ppm (2-3 ft bgs)
- WSB-79 = 22 ppm (2-3 ft bgs)

Although all September 2003 sample locations were satisfactorily delineated by the 75 ppm site-specific criteria, a total of 22 sample results indicated elevated levels of PCBs above the 2 ppm MCP RCS-1 criteria. Sample results for the September 2003 sampling event are presented in Table 6, Appendix C.

Based on analysis of the sample results obtained by WZB, HEA, H&A, and WESTON between July 1998 and September 2003, a risk assessment was conducted to determine the contaminants of concern (COCs) in soil for the Site. The risk assessment concluded the following COCs exist in soil at the Site: PCBs; carcinogenic polycyclic aromatic hydrocarbons (PAHs); metals (arsenic, lead, and cadmium), VPHs and EPHs. Detailed results of the risk assessment are presented in the *Human Health Risk Assessment* (Sundstrom, 2004) report, which is included in Appendix F of this document. A discussion of these results are presented in Section 6 of this CSA.

4.2.2 Groundwater

In July 1998, WZB installed and sampled five groundwater monitoring wells. The samples were analyzed for VOCs, pesticides, metals, SVOCs, VPHs, EPHs, and PCBs. Sample results indicated no exceedance above the RCGW-2 criteria for the parameters analyzed. The WZB monitoring well locations (MW-2, MW-2A, MW-3, MW-3A, and MW-4) are shown in Figure 4-2, sample results are presented in Table 7, and raw laboratory data are included in Appendix D.

In May 1999, HEA planned to resample the monitoring wells previously installed by WZB. Upon mobilizing the Site on 23 May 1999, HEA was only able to locate and develop one well (MW-1). On 2 June 1999, HEA returned to the Site, and installed three additional monitoring wells (MW-5, MW-6, and MW-7) within the vicinity of the former WZB monitoring wells (refer to Figure 4-2). Monitoring well installation logs are included in Appendix B. Groundwater sampling was conducted by HEA on 10 June 1999 using low-flow sampling techniques. Samples from each well were analyzed for VOCs by EPA Method 8260B and metals (arsenic, total chromium, and lead) by EPA Method 6010A. Samples collected from MW-1 and MW-4 were also analyzed for VPHs and EPHs by MDEP-specified methods. Sample results, which are included in Appendix D, indicated no exceedances above the RCGW-2 criteria for any of the parameters analyzed. Raw laboratory data are included in Appendix D.

In February 2003, WESTON planned to redevelop and sample the seven existing monitoring wells previously installed by WZB and HEA. None of the existing wells could be located during the WESTON site reconnaissance; therefore, WESTON installed four new 1.5-inch-diameter wells (MW-1, MW-5, MW-6, and MW-7) to collect the groundwater samples. These wells,

which are shown on Figure 4-2, were installed using a direct push track-mounted GeoProbe system. Groundwater samples collected from the wells were field-filtered and then shipped off-site for laboratory analysis. The samples were analyzed for VOCs by EPA Method SW-846/8026B, and for metals by methods 6010A and 7471A (RCRA-8 metals only). The laboratory analytical results, which are presented in Table 7 (Appendix C), indicate that vinyl chloride was detected in one downgradient well (MW-7) at a concentration that exceeds the RCGW-2 criteria for groundwater at the Site. There were no detections of VOCs above the RCGW-2 criteria in upgradient monitoring wells MW-1, MW-5, and MW-6, and no detection of metals at any of the four locations.

4.2.3 Sediment

In September 2002, H&A collected nine sediment samples from the Merrimack River for PCB analysis. The samples were collected from 0-1 ft from the river bottom using a hand auger. The samples were analyzed for PCBs only and results indicated exceedances above the National Ocean and Atmospheric Administration Threshold Effect Levels (NOAA TELs) for Aroclor 1260 at two sample locations (SED-4 and SED-7). Sample location SED-7 also had an exceedance for Aroclor 1254. Sample results are presented in Table 4, Appendix C.

In February 2003, WESTON collected an additional three sediment samples. Two samples were collected upstream of the Site (CB-1and RSED-1), and one sample was collected downstream of the Site (OUTFALL-1). The purpose of collecting additional sediment samples was to determine if sediment concentrations leaving the Site via the outfall adversely impact ecological receptors in the Merrimack River, determine if concentrations of COCs leaving the Site are less than or equal to those entering the Site, and determine if there are other potential contributors to sediment contamination in the Merrimack River (i.e., other Primary Responsible Parties). Sample results, which are included in Table 8 (Appendix C), show that levels of PCBs (Aroclor 1242 and Aroclor 1260) and metals (arsenic, cadmium, chromium, lead, and mercury) are detectable at concentrations that exceed the NOAA TELs in samples collected both upstream and downstream of the Site. With the exception of Aroclor 1242 and cadmium, the concentration of contaminants is lower at the downstream sample location (OUTFALL-1) compared to the two upstream sample locations (CB-1 and RSED-1). Based on these results, it is likely that contaminants detected in sediment samples are neither originating nor migrating in high

concentrations from Site sources; however, there is insufficient data available to definitely correlate results obtained downstream with those obtained upstream.

4.3 SOURCE CHARACTERIZATION

Potential source areas of contamination at the Site are described in the following subsections.

4.3.1 Soil

The Site is a commercial/industrial property with a residential area located within 500 ft of the site boundary. Consequently, Site soils have been classified by MDEP as RCS-1 for current and future conditions. Soil sampling data collected to date, as previously discussed in Subsection 4.1, indicate that PCBs, metals (specifically lead), and TPHs exist in both surface and subsurface soils in exceedance of MCP and/or EPA criteria. The majority of impacted soils are surficial soils that will be covered in the future by buildings and/or asphalt.

4.3.2 Groundwater

The Site is not located near any public drinking water supply sources, and there are no private water supplies used for drinking water within 500 ft of the property boundary. According to the Inspection Service Department (Health and Food Division) for the City of Lawrence, there are no wells of any type that exist within a 500-ft radius of the Site. Based on these criteria, the Site is classified as GW-2 by MDEP. Since all groundwater associated with the Site is expected to eventually discharge to a surface water body, it is also classified GW-3. Groundwater sampling data collected to date, as previously discussed in Subsection 4.1, indicated that elevated levels of VOCs and metals exist in Site groundwater. Although, Site groundwater is not likely to affect drinking water or surface water within 500 ft of the Site, it is a potential source of VOCs in air within future buildings on-site.

4.3.3 Baler/Press Room

Oily sludge (RTN 3-18431) observed on the baler/press room floor contains PCBs, TPHs, metals, and VOCs and may contribute to elevated concentrations of these constituents in samples collected elsewhere on the Site.

4.3.4 Municipal Sewer

Flooding and back-ups from the municipal sewer have been identified as potential sources of contamination at the Site.

4.3.5 Shear Residue/Berm Material

Soil materials intermixed with metals were previously stockpiled on-site, and may have contributed to contaminant loadings at the Site.

4.3.6 Abandoned Underground Storage Tank

An abandoned 500-gallon underground storage tank is located adjacent to the baler/press building.

4.4 VERTICAL AND HORIZONTAL EXTENT OF CONTAMINATION

Soil sampling has indicated that several areas of the Site contain elevated levels of PCBs in subsurface soils; however, the horizontal and vertical extent of some of these areas has not been adequately defined. To further assess the extent of contamination, it will be necessary to excavate soil from these areas and collect samples from the bottom and sidewalls of the excavations. As shown in Figure 4-1, lead has been detected in soil at two locations in excess of 2,000 ppm.

Volatile organic compounds have been detected in site groundwater, and could impact indoor air quality of future buildings constructed on-site. Further evaluation of soil gas within the vicinity of impacted groundwater is necessary to determine the vapor phase content of the VOC constituents from groundwater.

4.5 PRESENCE OF NON-AQUEOUS PHASE LIQUIDS

Free product (oily sludge) remains within the baler/press building and constitutes a potential threat to the surrounding environment. This situation has been previously reported to MDEP and assigned RTN 3-18431.

SECTION 5

ENVIRONMENTAL FATE AND TRANSPORT OF OIL AND/OR HAZARDOUS MATERIAL - CHARACTERIZATION OF EXISTING AND POTENTIAL MIGRATION PATHWAYS [30 CMR 40.0835(e)]

5. ENVIRONMENTAL FATE AND TRANSPORT OF OIL AND/OR HAZARDOUS MATERIAL - CHARACTERIZATION OF EXISTING AND POTENTIAL MIGRATION PATHWAYS [30 CMR 40.0835(e)]

There are several possible mechanisms by which COCs could migrate from the Site to environmental receptors. The COCs could be released to air through volatilization or dust generation; to groundwater by percolation or flow through contaminated soils; or to surface water through runoff or groundwater discharge.

Massachusetts Department of Environmental Protection Bureau of Waste Site Cleanup Numerical Ranking System Site Scoring Map (See Figure 3-1) for the Site shows site features used as scoring criteria located within 500 ft and 0.5 mile of the Site. The map shows the following with regard to potential receptors/nearby features:

- The Site is situated over a medium yield NPDWSA.
- The Site is located approximately 650 ft northeast of a protected open space area. There are no other protected open spaces, certified vernal pools, or Areas of Critical Environmental Concern within 0.5 mile of the Site.
- The Site is located approximately 600 ft from the Federal Emergency Management Agency 100-year floodplain of the Merrimack River and its associated wetlands habitat. There are no other wetlands habitats located within 0.5 mile of the Site.
- An intermittent stream tributary to the Merrimack River flows approximately 800 ft south of the Site.
- There are no other major, perennial, or intermittent streams or stream basins within 0.5 mile of the Site.
- There are two medium-yield potentially productive aquifers within 0.5 mile of the Site. These aquifers are located along the Merrimack River and are immediately adjacent to a medium-yield NPDWSA.
- There are no public water supplies, Approved Zone 2's, Interim Wellhead Protection Areas, or surface water supply Zone A's located within 0.5 mile of the Site.
- There are no MDEP-permitted Solid Waste Facilities within 0.5 mile of the Site.

To supplement the information above, Subsections 4.1 through 4.7 briefly describe potential exposure pathways for on-site or nearby receptors. A more complete description of exposure

pathways can be found in the *Human Health Risk Assessment* (Sundstrom, 2004) included as Appendix F of this document.

5.1 AIR

Fugitive dust emissions from wind or mechanical disturbances may occur from unpaved or unvegetated areas of the Site; therefore, COCs detected in surface soil are susceptible to migration via dust generation under current site conditions. Future paving or otherwise capping the Site soils would mitigate the potential for fugitive dust emissions.

5.2 SOIL

Contaminants present in soil can leach to groundwater or surface waters. The rate of contaminant movement through soils depends on the physical and chemical properties of the contaminants (i.e., solubility, density, viscosity, etc.) and the surrounding environment (i.e., rainfall, soil permeability, porosity, organic carbon content, etc.). The main COCs at the Site, PCB Arochlors, are considered relatively immobile in the environment and would not be expected to move readily through site soils.

5.3 GROUNDWATER

The rate of contaminant movement in groundwater systems is also influenced by the physical/chemical factors of the COCs and the surrounding environment. Once the COCs reach groundwater, they will be transported by advection and dispersion; however, for contaminants such as PCBs and metals that readily adsorb to soil particles, downstream migration is hindered by the sorption process. Based on the data collected in this assessment (refer to Section 4), VOCs and metals have been found to exist at detectable concentrations in site groundwater.

5.4 SURFACE WATER

The Merrimack River, which is located just east (and downgradient) of the property, could be impacted by site contaminants through run-off, groundwater percolation, and/or flow-through impacted soil/sediments. Under current Brownfields legislation, as long as future contaminant migration from the Site to the river is eliminated, new property owners will not be held responsible for historical impacts to the river.

5.5 SEDIMENT

In general, PCBs and some metals have low solubility in water and as a result are sorbed onto sediment particles that eventually settle in the bottoms of water bodies. The finer the sediment particles, the more easily PCBs and/or metals are adsorbed. Storms, or other high water flow events, can cause resuspension of PCB-laden sediment resulting in downstream migration of the contaminants. Based on the data collected in this assessment (refer to Section 4), PCBs (Aroclor 1242 and Aroclor 1260) and metals (arsenic, cadmium, chromium, lead, and mercury) have been found at detectable concentrations in sediments both upstream and downstream of the Site.

5.6 FOOD CHAIN

Polychlorinated Biphenyls are highly soluble in lipids and tend to accumulate in fatty tissue becoming more concentrated as they are passed through the food chain.

5.7 INDOOR AIR

Volatile organic compounds detected in soil or groundwater could result in exceedances of indoor air quality criteria. In addition, PCBs sorbed to soil particles could become airborne as respirable dust, although this is not likely in indoor air. This phenomenon would be more likely to occur in outdoor trenches or as the result of construction or other intrusive activities.

SECTION 6

RISK CHARACTERIZATION AND EXPOSURE ASSESSMENT [30 CMR 40.0835(g)-(h)]

6. RISK CHARACTERIZATION AND EXPOSURE ASSESSMENT [30 CMR 40.0835(g)-(h)]

A risk assessment was completed as part of this Phase II CSA to evaluate whether COCs detected in groundwater and soil at the Site pose a significant risk of harm to human health, public welfare or the environment, as defined in the MCP. A Method 3 Human Health Risk Assessment and a Stage I Environmental Screening Risk Assessment were performed to evaluate potential risks under current and reasonably foreseeable future conditions. Results of these assessments are summarized below, and presented in detail in the *Human Health Risk Assessment* (Sundstrom, 2004), which is included as Appendix F of this document.

6.1 EXPOSURE ASSESSMENT

The exposure assessment for the Site was conducted to identify current and reasonably foreseeable future exposure scenarios and complete exposure pathways by which the COCs detected at the Site may reach potential human receptors. Potential human receptors considered in the exposure assessment for both current and future site conditions included trespassers, site employees, and construction/utility workers.

It was assumed that under future conditions the surface soil would be covered either by buildings or asphalt pavement, and employees or visitors to the property would not be exposed to surface soils. Furthermore, since groundwater is impacted only by very low concentrations of VOCs, it is unlikely that future impacts to indoor air would be significant; therefore, this exposure pathway was not quantified. It was also assumed that ambient air would not be significantly impacted by the low VOC concentrations detected in soil and groundwater at the Site. In addition, PCBs were not detected in groundwater; thus, inhalation of PCB constituents in ambient air during excavation activities was also not considered significant.

At the conclusion of the exposure assessment, those exposure pathways considered to be complete included the following:

- **Trespassers:** Under current conditions, exposure through dermal contact, and/or incidental ingestion of surficial soil could occur
- **Employees:** Future employees at the Site have minimal risk of contact with COCs, and were not carried forward in the risk evaluation
- **Construction/Utility workers:** Workers could be exposed to impacted Site soils and/or groundwater through dermal contact, incidental ingestion, and/or inhalation while conducting excavations or other intrusive work at the Site

6.2 DISPOSAL SITE RISK CHARACTERIZATION

The risk assessment was performed in accordance with existing MCP and EPA guidance documents as referenced in the *Human Health Risk Assessment* (Sundstrom, 2004) (Appendix F).

As previously discussed, the Site is impacted with PCBs, PAHs, and metals in soil, and VOCs in groundwater. For the purposes of this assessment, it was assumed that VOC concentrations detected in groundwater would not result in significant impacts to ambient air or indoor air quality of future buildings constructed at the Site. Furthermore, VOCs were not detected in soil at significant concentrations; therefore, exposure via inhalation was not evaluated. It was also assumed that future employees at the Site would not be exposed to soil contaminants, because surficial soils will be covered by buildings and asphalt during redevelopment of the Site. Exposure was assessed for trespassers and construction/utility workers. Results of the assessment (refer to Appendix F) indicated that COCs in the soil do not pose a significant risk to trespassers with the exception of one "hot spot" identified within the vicinity of WSB-6 (refer to Figure 4-1). Risks to construction workers were identified in association with "hot spots" within the vicinity of WSB-6, CD-45, WSB-2, and the berms on the east/southeast side of the property (refer to Figure 4-1). Risks to utility workers were identified in association with "hot spots" within the vicinity of WSB-6 and CD-45 (refer to Figure 4-1). Based on these results it has been

concluded that a condition of No Significant Risk (NSR) exists at the Site with the following exceptions:

- Within the vicinity of the WSB-6 and WSB-2 "hot spots".
- Between 1-2 ft bgs at CD-45.
- Subsurface soils associated with the berms in the southern and eastern portions of the Site.

SECTION 7

CONCLUSIONS
[30 CMR 40.0835(l)]

7. CONCLUSIONS [30 CMR 40.0835(i)]

The following conclusions are based on current site data and the associated risk assessment results as presented in this Phase II CSA:

- Polychlorinated biphenyls exist in site soils at concentrations that require future response actions in accordance with both the MCP and Subpart O of TSCA.
- Metals (lead and cadmium) exist in Site soils at concentrations that exceed both MCP and EPA published standards.
- Free product (oily sludge) has been observed within the baler/press building and constitutes a potential threat to the surrounding environment. This situation was previously reported to MDEP, and was assigned RTN 3-18431.
- The Merrimack River, which is located just east (and downgradient) of the property, has been impacted by low levels of PCBs, which exceed environmental screening criteria. The source of the PCB contamination has not been determined; however, under current Brownfields legislation, as long as future contaminant migration from the Site to the river is eliminated, new property owners will not be held responsible for historical impacts to the river.
- Following any type of redevelopment of the Site involving paving and building construction over impacted soils, detectable concentrations of the COCs in soil and groundwater would pose NSR to human health or the environment with the exception of localized "hot spots" where construction/utility workers could be exposed to impacted soils via dermal contact, inhalation, and/or incidental ingestion.

APPENDIX A

LIST OF MAJOR REPORTS AND SELECT RELEVANT LEGAL CORRESPONDENCES

APPENDIX A

The following is a list of major reports and select relevant legal correspondence in the Tombarello & Sons, Inc. (Tombarello) file/paperwork. Copies of these reports, and/or results of the investigations described in these reports, can be made available upon request. In addition to the reports listed below, there are also numerous facility permits on file.

1. Response Action Outcome Statement

RTN 3-16817
Heat Transfer Fluid Release
John C. Tombarello & Sons, Inc
207 Martson Street
Lawrence, MA 01841

Prepared for:
Sprague Energy
126 River Road
Newington, New Hampshire

20 July 1998

Prepared by:
By New England Disposal Technologies, Inc. (NEDT)

The Response Action Outcome (RAO) resulted in closeout of Release Tracking Number (RTN) 3-16817, associated with the release of heat transfer oil on the site on 19 May 1998. However, Massachusetts Department of Environmental Protection (MDEP), in a request for information (2 December 1998), indicated that residual contamination at the property may be the result of other historic releases of other oil and/or hazardous materials (OHM), and not exclusively the result of heat transfer oil release.

2. Environmental Site Assessment

RTN 3-18126
John C. Tombarello & Sons, Inc.
Lawrence, Massachusetts

August 1998

By: W.Z. Baumgartner & Associates, Inc.
Environmental Consultants
P.O. Box 786
Brentwood, TN 37024-0786

The assessment was prepared in support of purchase of the property from Tombarello by American Recycling, Inc. Information presented in the assessment indicated the presence of OHM exceeding Massachusetts Contingency Plan (MCP) Reportable Concentrations on the property. On 31 March 1999, MDEP issued a *Notice of Responsibility (NOR)* and *Interim Deadline Letter* to both Tombarello and American Recycling, based on information contained in the documents listed above. A new RTN (3-18126) was assigned. Polychlorinated biphenyl (PCB) concentrations noted in the site assessment were interpreted by MDEP as constituting an Imminent Hazard Condition.

3. ***Environmental FirstSearch(TM) Report***
Target Property: 207 Marston St., Lawrence MA
Prepared for: Higgins Environmental Associates, Inc.

21 April 1999

Prepared By: DataMap Technology Corporation

This report was used in formulation of the IRA Plan.

4. ***Immediate Response Action Plan***
RTN 3-18126
John C. Tombarello & Sons, Inc
207 Martson Street
Lawrence, MA 01841

Prepared By: Higgins Environmental Associates, Inc.

21 April 1999

This plan was written in response to the *NOR* letter described in No. 2 above. The plan provided for removal of residual stockpiled soils associated with RTN 3-16817, as well as collection and analysis of surface soils and resampling and analysis of groundwater previously sampled in support of document No. 2.

5. ***Modified Immediate Response Action Plan***
RTN 3-18126
John C. Tombarello & Sons, Inc
207 Martson Street
Lawrence, MA 01841

1 June 1999

Prepared By: Higgins Environmental Associates, Inc.

6. ***Immediate Response Action Status Report***
1 June 1999 status update
RTN 3-18126
John C. Tombarello & Sons, Inc
207 Marston Street
Lawrence, MA 01841

28 July 1999

Prepared By: Higgins Environmental Associates, Inc.

Summarized site sampling activities and results, and addressed imminent hazard conditions, through installation of a perimeter fence to limit access to the property by children. Polycyclic Aromatic Hydrocarbons (PAHs), PCBs, and

7. ***MCP Options and Deadlines***
RTN 3-18126
John C. Tombarello & Sons, Inc
207 Martson Street
Lawrence, MA 01841

Revised 19 August 1999

Prepared By: Higgins Environmental Associates, Inc.

8. ***Response Action Outcome Statement and Supporting Information***
RTN 3-18431
Threat of Release Condition
Baler/Press Building
207 Marston Street
Lawrence, Massachusetts

Prepared For: American Recycling, Inc.

23 August 1999

Prepared By: Higgins Environmental Associates, Inc.

The RAO was filed, but not accepted by MDEP. As a result, RTN 3-18431 remains open and is now linked with 3-18126.

9. ***Field Inspection Notes***
Bureau of Waste Site Cleanup
Audits and Site Management Branch
Re: Former Tombarello & Sons

By Commonwealth of Massachusetts
Department of Environmental Protection

10. ***Administrative Consent Order and Notice of Noncompliance***
File No. ACOP-NE-00-9013-123
In the Matter of:
American Recycling of Massachusetts, Inc.
d/b/a Tombarello & Sons

Filed by Commonwealth of Massachusetts
Executive Office of Environmental Affairs
Department of Environmental Protection

This Order established deadlines for accomplishing MCP milestones for the property, including completion of Phases 2 through 5 and RAO of the Site.

11. ***Notice of Enforcement Conference***
Re: American Recycling of Massachusetts, Inc.
207 Marston Street
Lawrence, MA 01841

By Commonwealth of Massachusetts
Executive Office of Environmental Affairs
Department of Environmental Protection

12. ***Phase I Requirements/Tier Classification***
RTN: 3-18126
207 Marston Street
Lawrence, Massachusetts
File No. 12671-040

Prepared by: Haley & Aldrich, Inc. (for MDEP)

31 March 2000

Site Classified as Tier 1C in accordance with 310 CMR 40.0000.

13. ***Immediate Response Action (IRA) Completion Report***
RTN 3-18126
American Recycling of Mass., Inc.
207 Marston Street
Lawrence Massachusetts

Prepared by Haley and Aldrich, Inc. (for MDEP)

15 May 2001

This report summarized the following IRA findings:

- Polychlorinated biphenyl concentrations exceeding 10 milligrams per liter remained at the property in near surface soils
- The condition triggering an Imminent Hazard under the MCP had been abated via erection of a fence, controlling access to the property by children
- Groundwater sampling indicated that groundwater contaminant concentrations did not exceed RCGW-2 values.

14. ***Scope of Work***
Phase II Comprehensive Site Assessment
American Recycling of Mass., Inc.
d/b/a John C. Tombarello & Sons
207 Marston Street
Lawrence, Massachusetts
RTN 3-18126, 3-18431

Prepared by: Haley & Aldrich, Inc.

March 2002

This plan was written to address residual soil PAH, metals, and PCB contamination in surface soil, as well as to investigate other MDEP concerns, including utility lines and other potential release to/from these lines, sediment contamination in the Merrimack River which flows east of the site.

Notes:

[1]Composite samples comprise two grab samples

[2]Yellow highlighting indicates result is > 2ppm RCS-1 criteria, but < 75ppm site-specific criteria. Purple highlighting indicates result is >75ppm site-specific criteria.

[3]To account for the 2 grab samples that comprise each two-point composite, these results were doubled prior to comparing to the 2ppm RCS-1 criteria and/or the 75ppm site-specific criteria.

ft bgs = feet below ground surface

PCB = polychlorinated biphenyl

ppm = parts per million

U = Not detected at associated numerical reporting limit.

Notes:
[1]Grid location represents former composite sample location from July 2003, where the composite result exceeded the site specific criteria of 75ppm.
ft bgs = feet below ground surface
ppm = parts per million
PCB = polychlorinated biphenyl
U = Not detected at associated reporting limit.
Yellow highlighting indicates result is > 2ppm RCS-1 criteria, but < 75ppm site-specific criteria. Purple highlighting indicates result is >75ppm site-specific criteria.

Mr. Jonathan Higgins
Higgins Environmental Assoc.
19 Elizabeth St.
Amesbury, MA 01913

Job Name	**: 03014-Lawrence**	**Laboratory #**	**: 99040303**
Job #	**: 03014-99**	**Purchase Order #**	**: 03014-99**
Location	**: Massachusetts**	**Control #**	**: 20122,20123,20124**

Dear Mr. Higgins,

Enclosed please find the laboratory results for the above referenced samples which were received by the Chemserve sample custodian, under chain of custody control number 20122, 20123 & 20124 on April 29, 1999. Samples were collected by Jonathan Higgins on April 28, 1999. Any abnormalities to the samples on receipt would be noted on the enclosed chain of custody document. This report is not valid without a completed Chemserve chain of custody with the corresponding control number, attached.

All samples analyzed by Chemserve are subjected to quality standards. These standards are either as stringent or more stringent than those established under 40 CFR Part 136, state certification programs, and corresponding methodologies. Chemserve has a written QA/QC Procedures Manual which outlines these standards, and is available, upon request, for your reference. Unless otherwise stated on the Chain of Custody or within the report, all holding times, preservation techniques, container types, and analytical methods are analogous with those outlined by the U.S. EPA.

I certify that I have reviewed the above referenced analytical data and state forms, and I have found this report within compliance with the procedures outlined in the Chemserve QA/QC Procedures Manual.

Ellen Abrams - QA/QC Administrator

Jay W. Chrystal - President/Laboratory Director

This report contains 58 pages.

June 22, 1999

Mr. Jonathan Higgins
Higgins Environmental Assoc.
19 Elizabeth St.
Amesbury, MA 01913

Job Name	**: 03014-Lawrence**	**Laboratory #**	**: 99060126**
Job #	**: 03014-99**	**Purchase Order #**	**: 03014-99**
Location	**: Lawrence MA**	**Control #**	**: 28831**

Dear Mr. Higgins,

Enclosed please find the laboratory results for the above referenced samples which were received by the Chemserve sample custodian, under chain of custody control number 28831 on June 11, 1999. Samples were collected by Jonathan Higgins on June 10, 1999. Any abnormalities to the samples on receipt would be noted on the enclosed chain of custody document. This report is not valid without a completed Chemserve chain of custody with the corresponding control number, attached.

All samples analyzed by Chemserve are subjected to quality standards. These standards are either as stringent or more stringent than those established under 40 CFR Part 136, state certification programs, and corresponding methodologies. Chemserve has a written QA/QC Procedures Manual which outlines these standards, and is available, upon request, for your reference. Unless otherwise stated on the Chain of Custody or within the report, all holding times, preservation techniques, container types, and analytical methods are analogous with those outlined by the U.S. EPA.

I certify that I have reviewed the above referenced analytical data and state forms, and I have found this report within compliance with the procedures outlined in the Chemserve QA/QC Procedures Manual.

Ellen Abrams - QA/QC Administrator

Jay W. Chrystal - President/Laboratory Director

Jim Ricker
Weston Solutions, Inc.
One Wall Street
Manchester , NH 03101

Dear Jim Ricker:

We appreciate this opportunity to provide you with our analytical services. ESS Laboratory is committed to providing the highest quality service. Our dedication to each client includes responsiveness to emergencies, dependable, well-written reports, and client services, which include the availability of all analysts to answer your inquiries.

Enclosed is your data report. The invoice for this project is being forwarded to your Accounts Payable Department unless other arrangements have previously been made with the laboratory. Samples will be disposed of thirty days after the final report has been mailed. If you have any questions or concerns, please feel free to call our Customer Service Department. We value our continued relationship and look forward to hearing from you in the future.

Sincerely,

ESS LABORATORY

Laurel Stoddard
Laboratory Director

CERTIFICATE OF ANALYSIS

PROJECT NARRATIVE
PAGE ONE OF THREE

CLIENT: Weston Solutions, Inc.
CLIENT PROJECT ID: Tombarello
ESS PROJECT ID: 03020133

Sample Receipt
1 Aqueous sample, 5 Ground Water samples and 32 Soil samples were received on February 14, 2003 for the analysis specified on the enclosed Chain of Custody Record.

Analytical Summary
The project as described above has been analyzed in accordance with the ESS Quality Assurance Plan. This plan utilizes the following methodologies: US EPA SW-846, US EPA Methods for Chemical Analysis of Water and Wastes per 40 CFR Part 136, APHA Standard Methods for the Examination of Water and Wastewater, American Society for Testing and Materials (ASTM), and other recognized methodologies. The analyses with these noted observations are in conformance to the Quality Assurance Plan. In chromatographic analysis, manual integration may be used instead of automated integration because it produces more accurate results.

Metals Analysis (Soil)
ESS Laboratory utilized the established linear dynamic range to determine acceptable analytical results.
The batch duplicate was outside of the recommended range for Arsenic due to matrix interferences.
The batch Matrix Spike/Matrix Spike Duplicates were outside of the recommended ranges for Barium, Lead and Mercury due to matrix interferences.

Polychlorinated Biphenyls Analysis
Surrogates were diluted outside of the calibration ranges for samples 03020133-06, 03020133-07, 03020133-10, 03020133-11, 03020133-15, 03020133-20, 03020133-20MS, 03020133-20MSD and therefore could not be accurately quantitated.
The batch Matrix Spike/Matrix Spike Duplicate was outside of the recommended range for Arochlor 1016 due to matrix interferences. This analyte was biased high.
The batch Matrix Spike/Matrix Spike Duplicate was outside of the recommended range for Arochlor 1016/1260 due to dilution.
Surrogate recovery was outside of the recommended range for sample 03020133-29.
Surrogate in sample 03020133-36 was flagged with an "M" qualifier. This surrogate could not be accurately quantitated due to matrix interferences.

PROJECT NARRATIVE
PAGE TWO OF THREE

CLIENT: Weston Solutions, Inc.
CLIENT PROJECT ID: Tombarello
ESS PROJECT ID: 03020133

Volatile Organics Analysis
Blank Spike was outside of the recommended range for 2-Butanone and Vinyl Acetate. These analytes were biased high, however, samples were non detect for these analytes.
Blank Spike was outside of the recommended range for Acetone. This analyte was biased high.
The batch Matrix Spike/Matrix Spike Duplicate was outside of the recommended range for 2-Butanone, 2-Hexanone, 4-Methyl-2-Pentanone and Vinyl Acetate due to matrix interferences. These analytes were biased high, however, samples were non detect for these analytes.
The batch Matrix Spike was outside of the recommended range for Acetone and Methyl tert-butyl ether due to matrix interferences.

EPH Analysis
The following modification to the MASS EPH Method was performed: The Aromatic Fraction and Target PAH analytes were analyzed by GC/MS.
Nonane has proven to be a poor performer for this methodology. Laboratory generated limits are used to assess quality control data.
The batch Matrix Spike was outside of the recommended range for Nonane, Nonadecane and Naphthalene. These analytes were biased low.
The batch Matrix Spike was outside of the recommended range for Pyrene and Chrysene. These analytes were biased high.
Surrogate was diluted outside of the calibration range for samples 03020133-04, 03020133-21, 03020133-26, 03020133-29, 03020133-36 and therefore could not be accurately quantitated.

No other observations noted.

This signed Certificate of Analysis is our approved release of your analytical results. Beginning with this Project Narrative, the entire report has been paginated. The Chain of Custody is the final report page. This report should not be copied except in full without the approval of the laboratory.

PROJECT NARRATIVE
PAGE THREE OF THREE

CLIENT: Weston Solutions, Inc.
CLIENT PROJECT ID: Tombarello
ESS PROJECT ID: 03020133

CERTIFICATION

Were any significant modifications made to the MADEP VPH and EPH method?
__No X Yes – Details Above

Were all QA/QC procedures REQUIRED by the VPH and EPH method followed?
X Yes __ No – Details Above

Were all performance/acceptance standards for required QA/QC procedures achieved?
__Yes X No – Details Above

I attest under the pains and penalties of perjury that, based upon my inquiry of those individuals immediately responsible for obtaining the information, the material contained in this report is, to the best of my knowledge and belief, accurate and complete.

End of project narrative.

Laurel Stoddard/Eric Baanante

Laboratory Report

James Ricker
Weston Solutions, Inc.
1 Wall Street
Manchester, NH 03102

PO Number: None
Lab Number: 5965
Date Received: 07/15/03

Project: Former Tombarello+ Sons Site

Attached please find results for the analysis of the samples received on the date referenced above.

Unless otherwise noted in the attached report, all test methods met the requirements of Resource Laboratories, LLC (RL) Quality Assurance Plan, Standard Operating Procedures (SOP) and the National Environmental Laboratory Accreditation Conference (NELAC). Any footnotes included to describe the results provided are described in the attached report.

Resource Laboratories, LLC maintains certification with the agencies listed below.

We appreciate the opportunity to provide laboratory services. If you have any questions regarding the enclosed report, please contact the laboratory and we will be glad to assist you.

Sincerely,
Resource Laboratories, LLC

Susan Sylvester
Principal, General Manager

Laboratory Report

Jim Ricker
Weston Solutions, Inc.
1 Wall Street
Manchester, NH 03102

PO Number: None
Lab Number: 6166
Date Received: 09/03/03

Project: Former Tombarello & Sons Site

Attached please find results for the analysis of the samples received on the date referenced above.

Unless otherwise noted in the attached report, all test methods met the requirements of Resource Laboratories, LLC (RL) Quality Assurance Plan, Standard Operating Procedures (SOP) and the National Environmental Laboratory Accreditation Conference (NELAC). Any footnotes included to describe the results provided are described in the attached report.

Resource Laboratories, LLC maintains certification with the agencies listed below.

We appreciate the opportunity to provide laboratory services. If you have any questions regarding the enclosed report, please contact the laboratory and we will be glad to assist you.

Sincerely,
Resource Laboratories, LLC

Susan Sylvester
Principal, General Manager

Quality Control Report

RESOURCE LABORATORIES, LLC.

Case Narrative
Lab # 6166

Sample Receiving and Chain of Custody Discrepancies
Samples were received in acceptable condition, at 3 degrees C, in accordance with sample handling, preservation and integrity guidelines.

Method Blank
No exceptions noted.

Surrogate Recoveries
The surrogate recovery for decachlorobiphenyl in sample 6166-10 was 172%. Co-eluting compounds are suspected as being contributors to the elevated recovery limit. The surrogate recovery for decachlorobiphenyl in sample 6166-32 was 174%. Co-eluting compounds are suspected as being contributors to the elevated recovery limit. No other exceptions noted.

Laboratory Control Sample Results
No exceptions noted.

Matrix Spike/Matrix Spike Duplicate/Duplicate Results
Sample 6166-09 was analyzed as a matrix spike/matrix spike duplicate. The surrogate recoveries and the RPD results did not meet acceptance criteria due to a problem with extraction, the solvent volume was not maintained. No other samples were impacted by this problem.

Sample 6166-27 was analyzed as a matrix spike/matrix spike duplicate. The percent recoveries were 413% and 440%. The elevated percent recoveries are due to the presence of aroclor 1260 in the sample, which shares peaks with the spike standard of aroclor 1254.

No other exceptions were noted.

Other
Non target compounds were noted in sample 6166-23. No other exceptions noted.

APPENDIX E

TOMBARELLO DATA EVALUATION SUMMARY

From: Quigley, Diane
Sent: Monday, April 12, 2004
To: Pam Hoskins
Cc: Jim Ricker
Subject: Tombarello Data Evaluation Summary

PCB data (analyzed by SW-846 Methods 8082) from soil samples collected on September 2, 2003 were reviewed (Lab number 6172 and 6166). The samples were analyzed by Resource Laboratories of Portsmouth, New Hampshire. The data was reviewed in accordance with the U.S. EPA New England Region I Data Validation Functional Guidelines for Evaluating Environmental Analyses (December 1996), the MADEP MCP Data Quality Enhancement Program criteria for presumptive certainty, and the quality control limits stated in the project specific QAPP. The following QC indicators were reviewed; holding time, method blanks, surrogate recoveries (TCMX and DCB), matrix spike recoveries and laboratory control spike recoveries.

Because the laboratory was not informed that this site needed to meet the MADEP MCP presumptive certainty QC criteria, the laboratory did not submit a MCP Response Action Analytical Report Certification Form nor did they comply with all of the laboratory's reporting requirements under the MCP Data Quality Enhancement Program. For example, the LCS and MS/MSD were not spiked with 1016 and 1260 as specified in the MADEP CAM. They were spike with Aroclor 1254 which was a contaminant of concern. Also, the QC recovery limits were 30 to 150 rather than 40 to 140. However, an LCS and MS/MSD (both spike with 1254) were analyzed with the samples and did meet the laboratory specified QC limits except for one of the MS/MSD samples in lab package 6166. The recovery was above the QC limits due to matrix interference resulting in a possible high bias in the unspiked sample (WSB73-2) for the positive Aroclor 1254 result only.

All data that was reviewed met the project specific QC guidelines for method blanks, surrogate recoveries (at least one surrogate in each sample recovered within the 30 to 150 QC range), and holding time. One of the surrogates recovered above the QC limits in two of the samples in each lab package. This again would result in a possible high bias in the detected sample results only.

The only significant deviation from the MCP requirements for presumptive certainty was the failure of the laboratory to confirm positive Aroclor results on a second column. Resource Laboratories was contacted and verified that no confirmation had been done on these two laboratory packages. However, it is Weston's opinion that since the majority of the QC did meet the EPA Validation Guidelines and the laboratory QC guidelines, and only a possible high bias is indicated by the few QC failures, the overall quality of the data results is good and results that were reported by the laboratory are acceptable.

EXECUTIVE SUMMARY

A Human Health Risk Assessment was performed on behalf of Weston Solutions, Inc. (WESTON) to evaluate potential risks to human health under current and reasonably foreseeable future conditions at the former Tombarello & Sons property located in Lawrence, Massachusetts. The risk assessment was performed in accordance with the guidance published by the United States Environmental Protection Agency (USEPA) and the Massachusetts Department of Environmental Protection (MADEP).

The detailed evaluation of human health risks was divided into four major sections: hazard identification, dose-response assessment, exposure assessment, and risk characterization. Risks were evaluated with respect to exposure to chemicals detected in soil and ground water.

The hazard identification section describes the procedures used to identify chemicals of concern. The Site is impacted primarily with polychlorinated biphenyl compounds (PCBs), polycyclic aromatic hydrocarbons (PAHs) and metals in soil. Ground water is minimally impacted. Low concentrations of VOCs and some metals were detected. Exposure scenarios were described, exposure concentrations and doses were calculated, and risks were evaluated for the following:

- Trespassers, who could be exposed to chemicals detected in surface soil; and
- Construction workers and utility maintenance workers, who may be exposed to impacted soil at the property during excavation activities in the future.

It was assumed that under future conditions, the surface soil would be covered either by buildings or asphalt pavement. Therefore, employees or visitors to the property would not be exposed to surface soil. Because ground water is impacted only with very low concentrations of VOCs, it is unlikely that impacts to indoor air would be significant. Thus, this exposure pathway was not quantified. It was also assumed that ambient air would not be significantly impacted because VOC concentrations detected in ground water and soil were low. In addition, PCBs were not

detected in ground water. Thus, inhalation of chemicals in ambient air during excavation activities was also not considered significant. The results of this assessment indicate that chemicals detected in soil do not pose a significant risk to these receptors with the exception of several areas of discrete contamination. The concentrations of PCBs detected in surface soil in the vicinity of WSB-6 pose an unacceptable risk to trespassers, construction workers and utility maintenance workers. The concentrations of PCBs detected in samples collected between one and three feet below the surface in the area in the vicinity of CD-45 pose an unacceptable risk to construction workers and utility maintenance workers. The concentrations of PCBs detected in deeper soil in the vicinity of test pits BRM-TP-4, BRM-TP-5 and BRM-TP-9/9A where the soil is bermed pose an unacceptable risk to construction workers. In addition, the concentration of cadmium detected between one and two feet below the surface in the vicinity of WSB-2 poses an unacceptable risk to construction workers.

METHOD 3
RISK ASSESSMENT
FORMER TOMBARELLO & SONS SITE
207 MARSTON STREET
LAWRENCE, MASSACHUSETTS

1.0 INTRODUCTION

1.1 OBJECTIVE

On behalf of Weston Solutions, Inc. (Weston), a human health risk assessment was performed for the former Tombarello & Sons property located at 207 Marston Street in Lawrence, Massachusetts ("the Site"). The purpose of this study was to evaluate whether chemicals detected in soil and ground water pose a significant risk of harm to human health.

1.2 METHODS

This risk characterization was performed in general accordance with relevant guidance documents from the USEPA and the MADEP. This assessment of risk includes a description of the chemicals detected at the Site, their toxicological characteristics, and an evaluation of the potential human health risks associated with the presence of these chemicals at the Site. In accordance with relevant Brownfields legislation, exempting new buyers from responsibility for historic releases to environmental media, this assessment considers only those risks posed to on-site receptors and/or potential continuing releases to the environment. All future releases to both groundwater and surface water in the vicinity of the Site will be eliminated by either source removal or removal of transport pathways, such as storm drains, etc. Therefore, the river is not considered part of this Site in this assessment. In addition, because the site is a commercial/industrial property that will either be covered by buildings or asphalt pavement in

the future, exposure to ecological receptors will be negligible. Thus, an environmental assessment was not performed.

The report is organized as follows:

- Hazard identification;
- Dose-response information;
- Exposure assessment;
- Risk characterization; and
- Uncertainties.

All tables appear at the end of the text. Concentrations in ground water are reported in units of micrograms per liter (µg/l), which is equivalent to parts per billion (ppb), or in units of milligrams per liter, which is equivalent to parts per million (ppm). Concentrations in soil are reported in units of milligrams per kilogram (mg/kg), which is equivalent to ppm.

2.0 HAZARD IDENTIFICATION

The hazard identification process includes a review of the existing analytical database for each medium, tabulation of data with regard to detected chemicals, and selection of chemicals of potential concern that were considered further in the risk assessment.

2.1 SITE DEFINITION

The former Tombarello & Sons property is about 14 acres in size and is located at 270 Marston Street in Lawrence, Massachusetts. The Site for this assessment is defined as the former Tombarello & Sons Property. Marston Street is located on the western border of the Site, Hofmann Street is located on the northern border of the Site and Route 495 is located on the eastern border of the Site. The Sons of Italy Lodge abuts the Site to the south. The Merrimack River is located approximately 400 feet east of the Site. The Site and the area surrounding the Site are zoned for medium intensity industrial uses. The site is now vacant, but in recent years, it had been used as a metal recycling facility and scrap metal handling yard. The details are described in the *Phase 2 Comprehensive Site Assessment (CSA)* (Weston, 2004).

2.2 REVIEW OF THE ANALYTICAL DATABASE

The data set for this assessment includes laboratory analytical data. Field screening data are not included in the dataset. The data set includes soil and ground water data collected by W.Z. Baumgartner & Associates, Inc. (Baumgartner) in 1998, soil and ground water data collected by Higgins Environmental Associates, Inc. (HEA) in 1999, soil data collected by Haley & Aldrich (H&A) in 2001, and soil, sediment and ground water data collected by Weston Solutions in 2003. Weston performed an overall data quality review in accordance with the requirements of the Massachusetts Contingency Plan (MCP) and USEPA Region I and concluded that the data have been deemed to be of sufficient quality to be used in assessment of site risks.

The following guidelines will be used to evaluate soil, sediment and ground water analytical data and to develop a list of chemicals of potential concern for the Site. Chemicals reported by the laboratory as estimated concentrations (*i.e.*, flagged with a "J") will be considered to be representative of actual concentrations. Field duplicate samples will be averaged. A concentration of one-half of the detection limit will be used to represent the possible presence of a chemical in samples in which the chemical was reported as not detected, unless it had not been positively detected in any samples in that particular medium.

2.2.1 Soil

In July 1998, Baumgartner collected 15 soil samples between zero to 11 feet below the ground surface (bgs) from nine soil borings (SB-1, SB-2, SB-3, SB-4, SB-6, SS-7, SS-8, and SS-9). The samples were analyzed for semi-volatile organic compounds (SVOCs), RCRA 8 metals, volatile organic compounds (VOCs), pesticides and PCBs, and total petroleum hydrocarbons (TPH) (gasoline and diesel range organics). The TPH data will not be included in the assessment.[1] Figure 4-1 of the CSA (Weston, 2004) shows the locations of these samples.

In April 1999, HEA collected 24 soil samples between zero and six inches below the ground surface from eight locations. These locations included four samples on the south east side of the Site in the vicinity of Weston monitoring well MW-7 (Baumgartner location SB#5); five samples in the vicinity of Baumgartner SS#8, five samples in the vicinity of Baumgartner SS#7; six samples in the vicinity of Baumgartner location SB#6 (Weston monitoring well MW-5), and one sample from the following locations: F7, F2, A11, and SB2-SS1. The samples were analyzed for extractable petroleum hydrocarbons (EPH) and polycyclic aromatic hydrocarbons (PAHs), cadmium and lead, volatile petroleum hydrocarbons (VPH) and target VOCs (including benzene,

1 Note that HEA subsequently collected VPH and EPH samples in the locations where TPH was detected by Baumgartner. The EPH/VPH data will be used to assess risks due to petroleum compounds.

toluene, ethylbenzene, xylenes, naphthalene, and methyl-t-butyl ether), VOCs, and PCBs. Figure 4-1 of the CSA (Weston 2004) shows the locations of these samples.

In September 2001, Haley and Aldrich collected 35 soil samples between zero and 15 feet below the ground surface. The samples were collected primarily on the eastern/southeastern portions of the Site and in the vicinity of the Bailer Press Building. The samples were analyzed for PCBs. Figure 4-1 of the CSA (Weston, 2004) shows the locations of these samples.

In February 2003, Weston collected 28 soil samples from borings WSB-1 through WSB-12 and WSB-14 at depths between zero and 7 feet below the ground surface. The samples were analyzed for PCBs, EPH and PAHs, and RCRA metals. In July 2003, Weston collected 15 additional samples from borings WSB-16 through WSB-18, WSB-21 and WSB-22 between zero and three feet below the ground surface in the vicinity of boring WSB-12. In addition, Weston collected 18 additional samples from borings WSB-25 through WSB-28, WSB-30, WSB-31, and WSB-32 between zero and three feet below the ground surface in the vicinity of boring WSB-6. The samples were analyzed for PCBs. Also, in July 2003, 44 composite samples were collected at depths of zero to one or one to three feet below the surface. The Site was divided into grids and one composite sample was collected from every two grid areas.[2] The samples were analyzed for PCBs. In September 2003, Weston collected discrete samples for PCB analysis from the locations that made up the composite samples with the elevated concentrations. Each location included five samples at three depth intervals (0-1' bgs, 1-2' bgs and 2-3' bgs) (one from the actual composite location, and one 10 ft off in each direction with the exception of hot spot DE-12, where only 3 perimeter samples could be collected because of the loading dock). Samples from the central boring in each grid area were analyzed, and if the results indicated total PCB concentrations of 37.5 ppm or higher, then samples from the other four perimeter locations were also analyzed to delineate lateral extent. Figure 4-1 of the CSA (Weston, 2004) shows the locations of these samples.

2 The property was divided into squares approximately 100 x 200 feet in size. The grid lines were labeled 1 through 6 (west to east) and A through M (north to south) (see Figure 4-1, Weston, 2004).

Table 1 presents a summary of the soil analytical data collected between zero and one foot below the surface and between one and three feet below the surface.[3] Samples that were collected across both depth intervals were considered in each summary. For example, results of a sample collected between zero and two feet below the surface was assumed to represent concentrations that could be present in the surface (*i.e.*, 0-1' bgs) or in the subsurface (*i.e.*, 1-2' bgs). Composite samples from two locations with elevated concentrations that were replaced by discrete samples at each of the locations were not included in the table. In other words, the composite samples collected at grid locations CD-35, DE-13, FG-13, FG-35, and JK-46 were replaced with discrete samples WSB-73 (at location CD-34) , WSB-77 through WSB-80 (at location CD-45), WSB-65 (at location DE-23), WSB-70 (at location DE-12), WSB-56 (at location FG-23), WSB-61 (at location FG-12), WSB-45 (at location FG-45), WSB-50 (at location FG-34), WSB-35 (at location JK-56), and WSB-41 (at location JK-45). Appendices A-1 and A-2 present the analytical data for the individual samples.

Table 2 presents a summary of the soil analytical data collected between three and 15 feet below the ground surface. Appendix A-3 presents the analytical data for the individual samples.

Chemicals of concern in soil were selected using a cumulative risk screen and USEPA Region 9 Preliminary Remediation Goals (PRGs) for industrial soil as screening benchmarks. For lead, a screening value equal to 800 mg/kg was selected (USEPA, Lead Workgroups Frequently Asked Questions). Compounds were grouped into those with noncarcinogenic effects and potential carcinogenic effects. For chemicals with noncarcinogenic effects, the maximum detected concentrations were divided by the PRG to obtain an estimated hazard index. For chemicals with potential carcinogenic effects, the maximum detected concentrations were divided by the PRG and multiplied by 1×10^{-6} to obtain an estimated potential carcinogenic risk. Any chemical with a hazard index greater than one or a carcinogenic risk greater than 1×10^{-6} was identified as a compound of concern. In addition, for the remaining chemicals the hazard indices and carcinogenic risks were summed to evaluate whether the cumulative hazard index was greater

3 Note that according to the USEPA, surface soil was considered to be located between zero and one foot below the surface.

than one or the total carcinogenic risk was greater than 1×10^{-6}. Table 3 presents the results. Chemicals of concern in soil include PCBs, carcinogenic PAH compounds, arsenic, lead, and cadmium. In addition, petroleum compounds (*i.e.*, VPH and EPH compounds) were also included because screening values have not been developed.

2.2.2 Ground water

Ground water samples were collected by Baumgartner in July 1998, by HEA in 1999 and by Weston in 2003. Monitoring wells locations are shown in Figures 4-2 of the CSA (Weston, 2004). The samples were analyzed for VOCs, pesticides and PCBs, SVOCs, metals, and petroleum compounds. The analytical data are presented in Table 4. In general, only low concentrations of VOCs were detected. Barium, chromium and low concentrations of lead were also detected in some wells. Petroleum compounds, SVOCs and PCBs were not detected in ground water.

2.2.3 Sediment

In February 2003, Weston collected a sediment sample from a catchbasin located on the property. Petroleum compounds, metals and low concentrations of PCBs were detected (Table 5). The results of this sample are not addressed further in this assessment. Since the concentrations detected are much lower than the concentrations of chemicals detected in soil, it was assumed that if risks to workers who could come into contact with impacted soil are within acceptable limits, then contact with sediment in the catchbasin would also be within acceptable limits. Moreover, as part of the remedial activities, source removal from potential transport pathways such as storm drains will be addressed.

3.0 DOSE-RESPONSE ASSESSMENT

The dose-response assessment presents data relating potential doses received from exposure to chemicals to potential health effects (response). Information is provided in this section relative to the dose-response relationships for the chemicals of concern, based on available laboratory animal studies and human epidemiology as reported in the USEPA's Integrated Risk Information System (IRIS) database, USEPA's Health Effects Assessment Summary Tables (1992; 1997), and USEPA's *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons* (1993). In some cases, dose-response information was not available from USEPA sources; in these cases, other sources of information including the MADEP were used.

3.1 ASSESSMENT OF NONCARCINOGENIC HEALTH EFFECTS

In accordance with USEPA guidance, chronic oral Reference Doses (RfD) or chronic Reference Concentrations (RfC) were used to evaluate noncarcinogenic effects. An RfD is a health-based criterion used to evaluate noncarcinogenic effects from exposures involving ingestion or dermal contact. Likewise, subchronic RfDs have been developed to estimate noncarcinogenic health effects from subchronic exposures. An RfC is a health-based criterion used to evaluate noncarcinogenic effects from inhalation exposures. Chronic RfDs and RfCs are estimates of daily exposure doses or concentrations for the human population (including sensitive sub-populations) that are likely to be without an appreciable risk of deleterious effects during a lifetime of exposure (USEPA, 1989). RfDs and RfCs are presented in Table 6.

3.2 ASSESSMENT OF CARCINOGENIC HEALTH EFFECTS

Carcinogens are considered by USEPA policy to lack a threshold of no adverse effects; this policy implies that any exposure carries some risk. Cancer potency factors, referred to as slope factors (SFs), have been derived to estimate risks resulting from oral and dermal exposures based

upon this assumption. A SF is equal to the slope of the dose-response curve and, when multiplied by the dose, provides an estimate of the upper 95 percent confidence interval of the incremental lifetime cancer risk, or probability of cancer occurring above normal background rates. Similarly, inhalation Unit Risks have been developed based on cancer slope factors or derived from inhalation studies to evaluate cancer risks resulting from inhalation exposures. SFs and inhalation Unit Risks for the chemicals of concern are presented in Table 6.

Carcinogens are classified by USEPA using a weight-of-evidence classification system to indicate the degree of confidence between chemical exposure and the likelihood of causing human cancer. Classifications are based primarily on the degree of evidence for cancer to occur based on human and animal studies. USEPA weight-of-evidence categories are: A, known human carcinogen; B1 or B2, probable human carcinogen (B1 indicates that limited human data are available; B2 indicates sufficient data in laboratory animals and inadequate or lack of evidence in humans); C, possible human carcinogen based on limited laboratory animal evidence and inadequate or lack of human data; D, not classifiable based on inadequate or no evidence; and E, no evidence of carcinogenicity to humans.

3.3 TOXICOLOGICAL PROFILES

General information and brief toxicological summaries for the chemicals of concern to human health at the Site are presented below. Where available, information has been derived from the IRIS database, from USEPA Health Effects Assessment Summary Tables (USEPA, 1992; 1997), and from the Agency of Toxic Substances and Disease Registry (ATSDR) Toxicological Profiles.

3.3.1 Polycyclic Aromatic Hydrocarbon Compounds

PAHs are a group of over 100 different compounds, which are found ubiquitously in the environment (ATSDR, 1995). PAHs are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances. They can be manmade or occur naturally. They can be

found in crude oil, coal, coal tar pitch, creosote, road and roofing tar, and food items. Most PAHs do not occur alone in the environment, but as a mixture of two or more compounds.

Several of the PAHs are used as synthetic intermediates in dye production (anthracene, acenaphthene, phenanthrene), in the synthesis of pharmaceuticals (anthracene), in the formation of polyradicals (fluorene), in the manufacture of explosives (phenanthrene), and in lining material to protect the interior of steel and ductile-iron drinking water pipes and storage tanks (fluoranthene). Other PAHs do not have any known uses, for example, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, benzo(a)pyrene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and pyrene.

PAHs are absorbed following ingestion. The amount of absorption depends upon the vehicle of administration. For example, the amount is enhanced if PAHs are solubilized in a vehicle that is readily absorbed. Although data are unavailable regarding the absorption of PAHs by inhalation in humans, laboratory animal experiments suggest that PAHs may be absorbed into the blood. Dermal absorption is also possible in humans, but it is not extensive.

Laboratory animal experiments suggest that PAHs are distributed predominantly to the lung, liver, kidney, gastrointestinal tract, and muscle tissue following inhalation. Following ingestion, laboratory animal experiments indicate that PAHs are initially distributed primarily to fat tissue then they are distributed to the liver, lung and kidney following a few hours. In contrast, other studies have shown that some PAHs are first distributed to highly perfused tissues such as the liver, blood, and brain. After a few hours they are distributed to fatty tissue. Still other studies have shown that some PAHs are distributed to the liver and kidneys and are rapidly eliminated thereafter. Following dermal exposure, although PAHs penetrate skin, very little is distributed to tissues. For example, only about 1.3 percent was detected in tissues of rats following dermal application of anthracene. PAHs are lipophilic compounds that readily penetrate cellular membranes and can remain in the body indefinitely; however, they can be metabolized to more water-soluble compounds and are thus more likely to be excreted. Metabolism of PAHs occurs in all tissues, but the degree of enzyme activity is different for different tissues. The amount and type of enzyme activity can also be influenced by exposure to other compounds, thus influencing

the rate of metabolism and the types of metabolites formed. Since PAHs have fairly similar structures, their metabolism is also fairly comparable. Following inhalation, a large fraction of the inhaled dose is excreted from the lungs with only small percentage excreted in the urine and feces. In contrast, following ingestion, about 80 to 90 percent is excreted in the feces. Following dermal exposure, the small amount that was absorbed through the skin is excreted in the urine and feces.

Adverse health effects attributed to PAHs, other than cancer, have generally not been observed in humans with the exception of adverse hematological and dermal effects. Although the data concerning hematological effects in humans are flawed with confounding factors, the evidence is substantiated with laboratory animal data showing that PAHs tend to attack rapidly proliferating tissues such as the bone marrow blood-forming cells. Benign skin tumors have been reported in humans, but these lesions are reversible. Workers exposed to substances containing PAHs have experienced chronic dermatitis. Laboratory animal evidence indicates that the lymphoid system, because of its rapidly proliferating tissues, is also susceptible to PAH-induced toxicity. Immunological effects have not been associated with exposure to PAHs in humans, but laboratory animal evidence indicates that immunosuppression may be caused by exposure to PAHs and the degree of immunosuppression may correlate with carcinogenic potency. Adverse hepatic effects have not been reported in humans, although mild hepatic changes have occurred in laboratory animals exposed to PAHs. Neurotoxic effects have not been reported in either humans or laboratory animals. The results of laboratory animal studies suggest that developmental effects may occur in humans. PAHs may also cause reproductive effects in humans. For example, data indicate that women who smoke cigarettes show a decrease in fecundity. Since the testes and ovaries contain rapidly proliferating cells, it is possible that reproductive toxicity may occur. The USEPA has not established RfDs for many of the PAHs. USEPA has, however, established RfDs for naphthalene, acenaphthene, anthracene, fluoranthene, pyrene, and fluorene. The RfD for naphthalene is equal to 2.0×10^{-2}. The RfD for fluoranthene and fluorene is equal to 4.00×10^{-2} mg/kg/day. The RfD for anthracene is equal to 3.00×10^{-1} mg/kg/day and for pyrene is equal to 3.00×10^{-2} mg/kg/day. The RfD for acenaphthene is equal to 6.00×10^{-2} mg/kg/day. PAHs of similar structures were used as surrogates for PAHs for

which specific RfDs have not been developed. USEPA has established an inhalation RfC for naphthalene equal to 3×10^{-3} mg/m^3.

Several PAHs have also been shown to be genotoxic in mammalian systems. Although PAHs have not been clearly identified as the causative agent, evidence exists to suggest that some PAHs are carcinogenic in humans following inhalation and dermal exposures. Cancers have been predominantly in the lung following inhalation exposures and in the skin following dermal exposures. This evidence is mostly from occupational studies of workers involved in coke production, roofing, oil refining, and coal gassification. It is impossible, however, to evaluate the contribution of any individual PAH to the total carcinogenicity of these mixtures because of the complexity of the mixtures and the presence of other carcinogens. Laboratory animal data, however, indicate that some of the PAHs are carcinogenic while others do not have carcinogenic potentials. USEPA classifies benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene as Group B2 carcinogens (*i.e.*, probable human carcinogen) based on the induction of several tumor types in laboratory animals. USEPA has established an oral slope factor equal to 7.30 (mg/kg/day)$^{-1}$ for benzo(a)pyrene, the most potent PAH. Carcinogenic risk estimates for mixtures of PAHs have often assumed that all carcinogenic PAHs are equipotent to benzo(a)pyrene. Recently, USEPA has developed a series of relative potency values as temporary guidance for the evaluation of carcinogenic risk of PAHs (USEPA, 1993). The estimated order of potential potencies of PAHs is as follows:

benzo(a)pyrene	1.0
benz(a)anthracene	0.1
benzo(b)fluoranthene	0.1
benzo(k)fluoranthene	0.01
chrysene	0.001
dibenz(a,h)anthracene	1.0
indeno(1,2,3-cd)pyrene	0.1

These potencies are used to adjust the slope factors of the individual PAHs compared with benzo(a)pyrene.

3.3.2 Polychlorinated Biphenyl Compounds

PCBs refer to a family of 209 individual compounds (ATSDR, 1995). PCBs produced in the United States are known by their industrial trade name, Aroclor. They were produced in the United States until 1974 for use in capacitors and transformers. PCBs were used because of their excellent dielectric and fire-resistant properties. PCBs produced in Japan and Germany are known as Kanechlors and Clophens, respectively.

Following oral exposure, gastrointestinal absorption is greater than 90 percent. Although data indicate that PCBs are absorbed via inhalation and dermal routes, the extent of absorption is less efficient. Due to their lipophilic nature, PCBs tend to accumulate in fatty tissues. PCBs initially distribute to the liver and muscle tissue and eventually they are redistributed to the fat, skin, and other fat-containing organs. PCBs are metabolized by the cytochrome P450 system. The metabolism of PCBs is dependent on the number and position of the chlorine atoms. Isomers with fewer chlorines are metabolized more readily than more chlorinated isomers. PCBs that are metabolized with more difficulty tend to be excreted via the feces, while the compounds with fewer chlorines are excreted via the urine.

Evaluation of the toxicity of PCBs is difficult because PCBs are mixtures of a variety of different congeners and impurities. The toxicity of the coplanar PCBs (dioxin-like) appears to be related to Ah receptor binding and subsequent synthesis of a variety of cellular proteins. The mechanism of toxicity of the other PCBs has not been established. Occupational studies have established that PCBs cause dermal and ocular effects. Effects such as chloracne, skin rashes, pigmentation of nails and skin, and burning eyes and skin have been associated with occupational exposure to PCBs. Similar effects have also been reported in laboratory animals exposed to PCBs via ingestion. Although PCBs have produced increases in serum liver-related enzyme levels following occupational exposure, these changes generally show inconsistent patterns, may be within normal ranges and have not been associated with liver dysfunction. Cytochrome P450 enzyme induction has been observed in the liver of humans, which may alter the metabolism of other substances and could lead to either increased or decreased toxicity of the other substances.

Liver damage has been observed in laboratory animals exposed via inhalation and ingestion. The liver damage in laboratory animals has been shown to be reversible prior to necrosis. Increased excretion of urinary porphyrins was observed in occupationally-exposed workers in one study. Although there is no evidence of porphyria in humans following exposure to PCBs, it is possible that porphyria may occur in humans at high doses of PCBs since an increase in urinary porphyrins followed by porphyria has been observed in experimental animals. Effects on the immune system have not been documented in humans, but immunosuppression has been observed in laboratory animals maintained on diets containing high concentrations of coplanar PCBs. One study reported a decrease in serum thyroxine levels in transformer maintenance workers, but other data concerning endocrine effects are not available for humans. The thyroid gland is, however, the most sensitive target organ in laboratory rats. Coplanar PCBs have been shown to act as anti-estrogens, while some non-planar PCBs have been shown to have estrogenic effects. Currently, the data are limited to acute studies so the long-term consequences are not known. Although hematological effects have not been reported in humans, a chronic oral study conducted in monkeys suggested that hematological effects could possibly occur. Some neurological effects have been reported in laboratory animal studies, but the significance of the results is not known. PCBs have not been shown to be teratogenic, but some studies have suggested that PCBs may cause neurodevelopmental effects. Although the developmental effects observed in humans cannot be specifically attributed to PCBs, the laboratory animal data appear to suggest similar results. Effects on reproduction appear to be species-specific. For example, conclusive information regarding reproductive effects has not been reported in humans, but complete reproductive failure has been observed in mink exposed to greater than 5 ppm PCBs in their diet. The susceptibility of mink to these effects may be related to their high Ah receptor affinity compared with other species. Reproductive effects have also been reported in rats, mice and monkeys. USEPA has established oral RfDs for Aroclor 1016 and Aroclor 1254 equal to 7.0×10^{-5} mg/kg/day and 2.0×10^{-5} mg/kg/day, respectively. RfDs have not been established for Aroclor 1248 or Aroclor 1260. A subchronic RfD equal to 5×10^{-5} mg/kg/day cited in HEAST (1997) was used for the construction worker scenario.

In general, PCBs have not been found to be mutagenic in either *in vitro* or *in vivo* assays. PCBs have been shown to cause liver cancer in rats. The data suggests that Aroclor 1260 has the greatest carcinogenic potential compared with Aroclor 1254 and other lower chlorinated PCBs. The liver tumors are, however, relatively non-aggressive, non-metastasizing, and not life-shortening. USEPA has concluded that the amount of evidence is sufficient to conclude that commercial PCB mixtures cause cancer in laboratory animals, but the available data do not indicate that PCBs cause cancer in humans. USEPA has categorized mixtures of PCBs as Group B2, probable human carcinogens. USEPA established an oral SF for PCBs equal to 2.0 $mg/kg/day^{-1}$.

3.3.3 Arsenic

Arsenic is the 20th most abundant element in the earth's crust (ATSDR, 1993). The most important compound for commercial use is arsenic trioxide, which is generated at copper and lead smelters and then purified. The principal uses are for wood preservation and for the manufacture of pesticides that are used in agriculture. Smaller amounts are used in the production of glass and in the electronics industry.

Studies of patients exposed to arsenic in cigarette smoke and occupational studies of workers exposed to arsenic dust in smelters suggest that between 30 and 60 percent of arsenic is absorbed following inhalation. Arsenic is well absorbed across the gastrointestinal tract as well. Laboratory animal studies suggest that dermally applied arsenic may initially bind to skin and may be absorbed slowly. Following ingestion or inhalation, arsenic is distributed throughout the body. Concentrations in hair and nails are slightly greater than the rest of the body. Arsenic is interconverted between the arsenate and arsenite forms by oxidation/reduction reactions and also undergoes methylation reactions. The majority of inhaled and ingested arsenic is excreted in the urine within a few days.

The primary effects of inhaled arsenic in humans are respiratory tract irritation, lung cancer and skin effects. Inhalation of dusts is irritating to the respiratory tract, but functional impairment is not typically observed. Acute ingestion of high doses may cause heart arrhythmias in humans.

Chronic ingestion of lower doses may cause damage to blood vessels resulting in loss of circulation referred to as "Blackfoot disease." This disease has only been reported in Taiwan; thus, other factors may also have been involved. Arsenic has, however, been shown to cause other less severe vascular effects in humans following chronic ingestion (*e.g.*, 0.6 to 0.8 mg/liter in drinking water) or inhalation (*e.g.*, chronic occupational exposures). Nausea, vomiting and diarrhea are common following ingestion of large doses. Effects on blood cells have been reported following ingestion but not inhalation. These effects are generally not observed in humans exposed to less than 0.07 mg/kg/day. Effects on the liver have been reported in humans following chronic ingestion of 0.019 mg/kg/day or more. The data suggest that the effects are primarily on the liver vasculature. The kidney is not a target organ. Both central nervous system effects, including confusion, impaired memory and hallucinations and peripheral nervous system effects, including numbness in the extremities, weakness and loss of reflexes have been observed following inhalation and ingestion of arsenic. Epidemiological studies typically indicate that central nervous system effects may occur following acute, high doses of arsenic while peripheral nervous system effects occur following chronic exposure to lower doses (0.019 to 0.5 mg/kg/day). Chronic ingestion of arsenic in drinking water (greater than 0.01 mg/kg/day) has also been shown to cause hyperkeratinization, hyperkeratinized warts, and hyperpigmentation. These lesions are very characteristic of arsenic exposure and appear to be the earliest observable signs of chronic exposure. Arsenic has been reported to cause developmental effects in laboratory animals, but only at doses that are also toxic to the mother. Therefore, it can not be concluded that arsenic causes developmental effects. Based on existing information, it is not known whether arsenic causes reproductive effects. USEPA has established an oral RfD equal to 3.0×10^{-4} mg/kg/day based on skin effects and possible vascular effects.

A number of studies have been performed to evaluate the mutagenic potential of arsenic. The data are inconclusive, but suggest that arsenic is not mutagenic or is only weakly mutagenic. Epidemiology data indicate that exposure to arsenic via inhalation increases the risk of lung cancer and ingestion of arsenic increases the risk of skin cancer. Some studies also suggest that ingestion of arsenic may increase the risk of liver, bladder, kidney, and lung cancers. Based on the increased risk of lung cancer, USEPA assigned arsenic to Group A by the inhalation route,

and based on the increased risk of skin cancer, USEPA assigned arsenic to Group A by the oral route. USEPA established an oral slope factor based on data from epidemiological studies of populations exposed to arsenic in drinking water equal to 1.5 $(mg/kg/d)^{-1}$. Recent evidence suggests, however, that this slope factor may overestimate cancer risks at low doses because arsenic is rapidly metabolized to nontoxic methylated forms, which would result in a non-linear dose-response curve.

3.3.4 Cadmium

Cadmium is present in the earth's crust in low concentrations (ATSDR, 1993). Small amounts are released into the environment by natural weathering processes, but the majority comes from anthropogenic activities such as mining and smelting operations, fuel combustion and application of phosphate fertilizers. Cadmium is taken up and retained by plants and animals. Thus, cadmium that has accumulated in the food chain may represent a significant source of exposure to humans. For people who smoke cigarettes, another significant source of cadmium is cigarette smoke. The primary uses for cadmium include the production of nickel-cadmium batteries and metal plating. It is also used in pigments and plastics and for alloys.

Suspensions of cadmium particles inhaled into the lung may be absorbed if they are deposited and retained in the lower regions of the lungs, primarily the alveoli. Thus, absorption depends on deposition, particle size and retention. Based on a model developed using data obtained from cigarette smokers, about 50 percent of inhaled cadmium may be deposited into the deeper regions of the lung (due to the very small size of cadmium particles in cigarette smoke) and, of the amount deposited, about 50 to 100 percent will be absorbed. In contrast, ingested cadmium is not very well absorbed. It is estimated that only about 3 to 5 percent may be absorbed, although absorption may be increased in individuals whose diet is deficient in iron, calcium and protein. Dermal absorption is slow and may be of concern only when concentrated solutions are in contact with the skin for several hours or longer. Cadmium does not cross the placenta very well, probably because it is bound to various proteins such as metallothionein and it is not found in breast milk in significant concentrations. Cadmium is widely distributed in the body, although the major fractions are located in the liver and kidney. It may be stored in the liver and kidneys

for as long as 30 years. Cadmium is transported in the blood by binding to red blood cells and proteins such as albumin and to some extent metallothionein. Cadmium is not metabolized. Cadmium is excreted predominantly in the feces. Most of the excreted cadmium represents the unabsorbed fraction. Absorbed cadmium is excreted about equally in the urine and feces.

Acute ingestion of high concentrations of cadmium may cause nausea and vomiting and acute inhalation of high concentrations of cadmium fumes may cause chemical pneumonitis in humans. The principal effects in humans from chronic exposure to lower levels are respiratory effects and kidney disease. Inhalation of cadmium has been shown to cause chronic obstructive pulmonary disease and progressive fibrosis of the lower airways, which may lead to emphysema. The primary target organ is the kidney. Of principal importance in the toxic effects of cadmium to the kidney is the role of metallothionein, an inducible protein synthesized by the liver as well as other tissues including the lungs and kidneys. Chronic exposure to low levels of cadmium results in an increased synthesis of metallothionein. It is thought that cadmium bound to metallothionein within tissues is essentially non-toxic. Thus, when the concentration of cadmium exceeds the binding capacity of metallothionein, toxicity may occur. It is postulated that cadmium binds to metallothionein in the liver and is transported to the kidney. Within the kidney cells, the complex is degraded and free cadmium is released. When the amount of unbound cadmium becomes high enough, kidney damage begins to occur. In contrast, there is also some evidence that the complex itself causes renal tubular damage. Although cadmium accumulates in the liver, there is no evidence that cadmium causes liver damage in humans, possibly because the synthesis of metallothionein is sufficient to bind the free cadmium. In contrast, acute high doses of injected cadmium have been shown to cause liver toxicity in laboratory animals, most likely because a high concentration of unbound cadmium reaches the liver. Cadmium has also been shown to cause bone pain and osteoporosis. Effects on the skeletal system are, however, only observed in individuals with severe kidney damage. The mechanism may be either via a direct effect on bones or via an indirect effect as a result of kidney damage, which causes altered calcium metabolism and Vitamin D activation. There is conflicting evidence from both human and laboratory animal studies regarding the effects of cadmium on the cardiovascular system. Some studies indicate that cadmium may cause a small

increase in blood pressure and other changes in cardiac function, but overall, the evidence suggests that these effects are not significant. Insufficient evidence exists to evaluate whether cadmium causes either developmental or reproductive effects. USEPA has established an oral RfD equal to 5.0×10^{-4} mg/kg/day for exposure to cadmium in water and an RfD equal to 1.0×10^{-3} mg/kg/day for exposure to cadmium in food. The RfDs are based on potential kidney effects in humans. An inhalation RfC is pending.

A number of studies have been performed to evaluate the mutagenic potential of cadmium. The overall results of these studies have been conflicting, but they suggest that cadmium may cause mutations in somatic cells but not in germinal cells. A number of epidemiological studies have suggested a relationship between inhalation of cadmium and lung and prostate cancer. Experimental data demonstrate that inhalation of cadmium increases the risk of lung cancer in laboratory animals. Studies in humans and laboratory animals do not demonstrate that ingestion of cadmium is carcinogenic. Based on these studies, USEPA has classified cadmium as Group B1 by inhalation. They have established an inhalation Unit Risk equal to 1.8×10^{-3} ($\mu g/m^3$).

3.3.5 Lead

Lead is used in commercial products because of its ease of casting, high density, low melting point, low strength, ease of fabrication, acid resistance, and chemical stability (ATSDR, 1991). Until recently, the transportation industry was the major end user of lead. It was consumed in batteries and as a gasoline additive. Other materials in which lead was used include construction materials, ammunition, electrical materials, television glass, paint, and ceramics. In recent years, the use of lead has markedly decreased because of its toxic effects.

Like many metals, suspensions of lead particles inhaled into the lung may be absorbed if they are deposited in the lower regions of the lungs, primarily the alveoli. Thus, absorption depends on particle size. Typically, the rate of deposition is about 30 to 50%. Once deposited in the alveoli, almost all lead is absorbed. Lead is not as well absorbed via the gastrointestinal tract. The gastrointestinal tract is, however, the primary site of lead absorption in children. About 50

percent is absorbed in young children compared to one to 15 percent for older children and adults. The rate is also affected by the solubility of the particular lead salt and by fasting. USEPA recommends a default value of 12% (USEPA, 2003). Dermal absorption is much less significant. For example, about 0.06% of lead in cosmetic preparations is absorbed. Once absorbed, lead is distributed to several distinct compartments — blood, bone and various soft tissues including liver, kidney, lungs, brain, *etc.* In blood, lead is partitioned between red blood cells (about 90%) and plasma. In adults, almost 95 percent of the total body burden of lead is found in bones. In children, however, only about 73 percent is found in bones. Lead has been shown to cross the placenta in humans and has been shown to transfer into breast milk in laboratory animals. Inorganic lead has not been shown to be metabolized. In contrast, organic lead compounds are metabolized in the liver by cytochrome P450 enzymes. Unabsorbed lead is excreted in the feces. Absorbed lead is excreted also excreted in feces with smaller amounts excreted in urine.

Although lead may affect almost every organ system in the body, the primary target organs/organ systems are the nervous system, blood cells, and kidneys, reproductive system, and cardiovascular system in males. The most sensitive effects occur in the central nervous system of children and infants. IQ deficits have been reported in children with blood lead levels as low as 10 to 15 µg/dl and hearing deficits may occur at levels only slightly greater. In children and adults, lead affects the peripheral nervous system. These effects are manifested at much higher blood lead levels (40 µg/dl). Lead has been show to cause anemia by several mechanisms including shortening the lifespan of red blood cells and impairing heme synthesis. In the past, a major problem in occupational settings was the effects of lead on kidneys. High concentrations of lead have been shown to cause acute toxicity in proximal tubular cells, and chronic exposure has been shown to cause interstitial nephropathy. The most sensitive effects observed in adult males is the effect on blood pressure. It is postulated that lead increases blood pressure via an effect on vascular smooth muscle. Colic, which is characterized by abdominal pain, constipation, cramps, nausea and vomiting, is an early symptom of lead poisoning in children and in workers. Definitive conclusions cannot be drawn regarding an association between lead exposure and congenital malformations. Lead has, however, been associated with growth retardation in

children. Lead also is clearly associated with adverse effects on neurobehavioral development. Lead has been associated with sterility in males. This effect is supported by laboratory animal data that shows gametotoxic effects in both male and female animals. USEPA has not established an oral RfD or an inhalation RfC for lead. USEPA has developed models to predict blood lead levels that can be compared to acceptable blood levels. In addition, USEPA has established soil screening concentrations equal to 400 mg/kg for residential sites and 1,200 mg/kg for commercial/industrial sites. In contrast, MADEP has established an oral RfD equal to 7.5×10^{-4} mg/kg/day. Use of the MADEP RfD to quantify health risks generally results in a more conservative estimate of health risks. In this assessment, risks due to lead were estimated using the RfD established by the MADEP.

A number of studies have been performed to evaluate the mutagenic potential of lead. The results of these studies have been conflicting, thus it is unclear whether lead may cause genetic damage. Human data do not provide evidence that exposure to lead increases the risk of cancer. The available data in laboratory animals indicate that high levels of lead cause kidney tumors. However, these tumors have not been reported at levels below those that cause toxicity. Since lead also increases renal tubular epithelial cell proliferation, it is likely that the increase in tumors is due to a non-specific response to hyperplasia. Nevertheless, USEPA has classified lead as Group B2. They have, however, recommended that a numerical estimate of cancer potency or risk based on such data should not be used.

3.3.6 Petroleum Hydrocarbons

Fuel oils are refined from crude petroleum and are categorized either as a distillate fuel or a residual fuel depending on the method of production (ATSDR, 1993). Fuel oils No. 1 and No. 2 are distillate fuels. Residual fuel oils such as fuel oil No. 4 and No. 6 are residues remaining after distillation or blends of such residues with distillates. They are complex mixtures of straight chain and cyclic aliphatic hydrocarbons and aromatic hydrocarbons. They are distinguished from each other primarily based on their boiling point ranges, chemical additives, and uses. Fuel oils are used in many types of engines, in lamps, heaters, furnaces, stoves, and as solvents.

Indirect evidence suggests that fuel oils can be absorbed following inhalation and ingestion. There is also some evidence that fuel oils can be absorbed across the skin. Very little information is available concerning the distribution, metabolism and excretion of fuel oils.

Very little is also known about the human health effects caused by fuel oils. Fuel oils are eye and skin irritants. Data are, however, limited for most other systemic effects. Fatigue, headaches and coordination and concentration difficulties may occur following acute inhalation of high vapor concentrations. Respiratory effects may occur following inhalation of or dermal contact with high concentrations of diesel fuel. Most of the respiratory effects that have been reported have, however, occurred following aspiration. Vomiting, diarrhea and abdominal cramps have also been reported following exposure to high concentrations of diesel fuel vapor. In laboratory animal experiments, liver and kidney damage and immunotoxicity have been reported following inhalation of or dermal contact with fuel oils. Currently, the available information regarding liver and immune system effects is insufficient to assess the relevance to human health. Kidney effects that have been reported in male rats are attributed to a sex- and species-specific response and are unlikely to occur in humans or other species. Epidemiological data do not suggest an association between exposures to fuel oils and cancer.

Gasoline was originally produced by simple distillation of crude oil (ATSDR, 1995). Today, gasolines are blended from several petroleum refinery process streams. After blending the streams, sulfur is removed and additives are added to improve the performance and stability of gasoline. For example, organic lead compounds were added as anti-knock agents; however, methyl-tert-butyl ether has gradually replaced the use of lead. Gasoline primarily contains short-chain alkanes, cycloalkanes and alkenes and some aromatics including alkanes, cycloalkanes, alkenes, and aromatics such as benzene, toluene, ethyl benzene, and xylenes.

Although all chemicals can produce toxic effects if exposure is sufficient, traditional risk assessment methods have recognized that the majority of the compounds present in petroleum products are much less toxic than benzene, toluene, ethyl benzene, xylenes (BTEX), n-hexane,

and 17 PAH compounds (which are also found in various petroleum products). Typically, risk was quantified for the more toxic compounds and was not quantified for the remaining hydrocarbon compounds (since it was assumed that the risk due to these remaining compounds would contribute relatively little to the overall risk estimate). MADEP has recommended an alternative method to evaluate the risks from petroleum hydrocarbons that is described in the documents *Characterizing Risk Posed by Petroleum Contaminated Sites: Implementation of the MADEP VPH/EPH Approach* (MADEP, 2002a), the *Background/Support Documentation for the Development of Publication Guidelines & Rules of Thumb* (MADEP, 2002b), and the *Draft Updated Petroleum Hydrocarbon Fraction Toxicity Values for the VPH/EPH/APH Methodology* (MADEP, 2002d). The approach evaluates the risk due to specific compounds individually (including BTEX and 17 PAH compounds as has been done in the past) and uses surrogate toxicity criteria to represent the toxicity of the remaining hydrocarbons within certain carbon ranges. To quantify the risks due to exposure to these remaining hydrocarbons, MADEP has proposed the RfD and RfC for n-hexane to represent the toxicity of alkanes and cycloalkanes with carbon chain lengths in the range of C_5 to C_8. The MADEP had proposed an RfD ten-times the RfD for n-hexane to represent the toxicity of alkanes and cycloalkanes with carbon chain lengths in the range of C_9 to C_{18}. Currently, the MADEP changed the RfD to a value adopted by the Total Petroleum Hydrocarbon Criteria Working Group (TPHCWG, 1997). They also changed the RfC based on their interpretation of a study cited by the TPHCWG and another study by Lund *et al.* (1995). MADEP proposed an RfD for eicosane to represent the toxicity of alkanes and cycloalkanes with carbon chain lengths in the range of C_{19} to C_{32}. However, they recently changed their recommendation to a value recommended by the TPHCWG. Finally, they have proposed an RfD for aromatic and alkene compounds with carbon chain lengths in the range of C_9 to C_{32} based on a naphthalene/2-methyl naphthalene mixture study.

These surrogate compounds overestimate the toxicity of the petroleum fractions. MADEP has recommended the RfD for n-hexane (0.06 mg/kg/d) as the surrogate RfD for all alkanes and cycloalkanes having carbon chain lengths C_5 to C_8. The RfD is based on the RfC established by the USEPA. The alkanes and cycloalkanes ranging from C_5 through C_8 cause central nervous system depression following acute exposure to relatively high concentrations or doses. This

general effect is common to most solvents following exposure to very high doses or concentrations not typical of an environmental exposure. The effect is also a transient effect. In addition to these acute effects, some solvents also cause other specific effects following subchronic or chronic exposure to lower doses or concentrations. For example, benzene causes hemopoietic toxicity (*i.e.*, effects on developing blood cells) and n-hexane causes peripheral neuropathies and male reproductive effects. The specific toxicities are often directly related to the metabolism of the solvent to a specific metabolite. For example, the mechanism by which n-hexane produces peripheral neuropathies and male reproductive effects is through a specific metabolite, 2,5-hexanedione. None of the other compounds in the aliphatic petroleum fraction are metabolized to this metabolite and none of the other compounds produce either effects on the peripheral nervous system or the male reproductive system. MADEP suggests that n-pentane, n-heptane and n-octane may be associated with peripheral neuropathies. There is, however, no reliable or consistent laboratory animal evidence for this assumption and the only animal or human studies suggesting these effects were confounded by co-exposure to n-hexane. Therefore, while it is true that acute exposure to high concentrations of aliphatic compounds having carbon chain lengths from C_5 to C_8 can cause central nervous system depression, the scientific literature does not suggest that these compounds other than n-hexane can cause peripheral neuropathies and reproductive effects following chronic exposure to lower concentrations typical of environmental exposures. Likewise, MADEP recommends using the inhalation RfC established by the USEPA for n-hexane (0.2 mg/m^3) for the entire C_5 to C_8 aliphatic fraction. Although these values are likely to overestimate the risks significantly, they were used in this assessment.

MADEP proposed an RfD for alkanes and cycloalkanes with carbon chains ranging from C_9 to C_{18} using the surrogate compound n-nonane (0.6 mg/kg/d). MADEP assigned an RfD for aliphatic hydrocarbons in this range equal to 10 times that of n-hexane primarily based on subchronic studies in rats and mice and on the fact that the Threshold Limit Values (TLVs) established by American Conference of Governmental and Industrial Hygienists (ACGIH) for n-nonane is 10-fold higher than that established for n-hexane. Recently, the MADEP changed

the RfD to a value adopted by the Total Petroleum Hydrocarbon Criteria Working Group (TPHCWG, 1997) (0.1 mg/kg/d).

The RfD adopted by the TPHCWG also appears to be very conservative. The RfD assigned to this group of compounds (0.1 mg/kg/d) was based on studies in rodents exposed to mixtures of aliphatic compounds ranging from C_9 to C_{16}. The RfD (0.1 mg/kg/d) developed from the data in the first study was based on some serum chemistry changes, organ weight increases and microscopic changes in several organs, which were reversible within the month. The effects were attributed to male rat nephropathy, which is irrelevant to humans, and the direct effect of introducing high concentrations of an irritating substance via an intubation tube into the stomach (TPHCWG, 1997). It should also be noted that irritation is a local, not a systemic effect, and the threshold for irritation is likely to be much higher than the RfD that has been developed by incorporating a safety factor equal to 5,000.[4] Thus, an RfD equal to 0.1 mg/kg/d is likely to overestimate potential effects in humans. The RfD (0.1 mg/kg/d) derived from the data in the second study was based on increased liver weights, which were observed in the high dose females (1,000 mg/kg/d). They indicated the NOAEL (No Observed Adverse Effect Level) was 100 mg/kg/d; however, liver weight increases were not observed in female rats dosed with 500 mg/kg/d; thus, it is unclear why the NOAEL dose was assumed to be 100 mg/kg/d rather than 500 mg/kg/d. Moreover, increased liver weight is generally not considered an adverse effect. It is an adaptive change likely due to increased metabolic enzyme concentrations. In fact, all treatment-related effects were reversible within the month. Based on the data in these two studies a more appropriate RfD would be 0.5 mg/kg/d based on a safety factor of 1,000 for the first study and a NOAEL dose of 500 mg/kg/d in the second study. In a third study, increases in hemoglobin levels and decreases in triglyceride levels were observed in male rats but the effects were not considered significant. Liver weight changes were observed in females and males but no histopathological effects were noted and the effects were disappeared following the recovery period. These effects were observed at concentrations of 500 mg/kg/d. The RfD derived from this study was also 0.1 mg/kg/d based on a NOAEL equal to 100 mg/kg/d. As discussed previously, increased liver weight is likely to be an adaptive change, which is transient,

4 Typically, safety factors range between 100 and 1000.

particularly since histopathological effects were not observed. A fourth study was cited in which male rats were dosed with jet fuel. The RfD for this study (0.75 mg/kg/d) was based on a NOAEL of 750 mg/kg/d. Based on these four studies, the RfDs ranged between 0.1 mg/kg/d and 0.75 mg/kg/d. Three of the studies suggest that the RfD should be between 0.5 mg/kg/d and 0.75 mg/kg/d. Thus, it is likely that an RfD equal to 0.1 mg/kg/d would overestimate health risks. Nevertheless, this value was used to estimate the risks for this fraction in this assessment.

The MADEP recommends an RfC for the C_9 to C_{18} aliphatic compounds equal to 0.2 mg/m^3 based on a study by Lund *et al.* and the TPHCWG RfC equal to 0.9 mg/m^3, which the MADEP adjusted to 0.3 mg/m^3. The TPHCWG proposed an RfC equal to 0.9 mg/m^3 based on two studies in which NOAEL levels were identified as 900 and 1000 mg/m^3. The MADEP suggests that the NOAEL levels were actually LOAEL levels because decreased body weights and increased liver and kidney weights were observed in males at these concentrations. However, the effects on body weight were questionable. In addition, male rat nephropathy was observed at all doses; thus, the effects are not considered significant or relevant to human health. Thus, the TPHCWG was correct that the RfC should be based on a NOAEL equal to 0.9 mg/m^3. The study by Lund *et al.* is difficult to interpret. Neurobehavioral studies generally involve measurements of electrical potentials in the brain or other non-specific endpoints that are presumed to reflect neurobehavioral or neuropsychological effects. However, interpretation of the results by the authors is generally subjective. Comparing the results to psychological disorders observed in painters, who are exposed to a wide variety of solvents, is questionable. The majority of scientific literature published indicates that the major effects of long chain aliphatic hydrocarbons are central nervous system depression and irritation (ACGIH, 1991; Clayton & Clayton, 1994). Exposure to low concentrations of aliphatic hydrocarbons has not been associated with long-term health effects in either humans or laboratory animals. It should also be noted that RfC for the C_9 to C_{18} aliphatic petroleum compounds recommended by the MADEP is more conservative than RfCs established by the USEPA for the target volatile organic compounds (VOCs) in petroleum such as ethylbenzene and toluene (RfC equal to 1.0 and 0.4 mg/m^3, respectively).[5] The majority of scientific evidence suggests that aliphatic petroleum compounds are much less toxic than the

5 Other examples include the RfCs for styrene (1 mg/m^3) or chlorinated solvents such as vinyl chloride (0.1 mg/m3)

target VOCs; thus, the toxicity factors recommended by the MADEP are likely to overestimate health risks significantly. A more appropriate value, yet still conservative, is the value proposed the TPHCWG (1 mg/m^3), which is used in this assessment.

MADEP had proposed an RfD (6 mg/kg/d) for alkanes and cycloalkanes with carbon chain lengths from C_{19} to C_{36} based on a NOAEL for eicosane equal to 6,000 mg/kg/d. However, the MADEP recently recommended an RfD equal to 2 mg/kg/d based on a study by the TPHCWG in which the NOAEL was identified as 2,000 mg/kg/d (the highest dose tested). Clinical effects were not observed in either study. In fact, it is likely that clinical effects would not have been observed in the second study at a dose equal to 6,000 mg/kg/d, but the animals were not dosed higher than 2,000 mg/kg/d in this study. Based on the data from these two studies, the NOAEL is still 6,000 mg/kg/d. Moreover, safety factors of 1000 were applied. Quantifying potential risks for compounds that have been shown to be relatively non-toxic using a very conservative RfD greatly overestimates the risks for these compounds. Changing the RfD from 6 mg/kg/d to 2 mg/kg/d is not warranted especially for compounds that have not been shown to cause toxic effects in any species including humans and are safe enough to be used as food additives.

The TPHCWG proposed 0.2 mg/m^3 as the RfC for C_9 to C_{16} aromatic compounds. The TPHCWG based the RfC on a NOAEL (900 mg/m^3) in a study performed in rats. The only observable effect was an increase in liver and kidney weights in male rats dosed with 1,800 mg/m^3. As discussed above, these effects are likely adaptive effects (increases in metabolic enzymes) and are probably transient. Thus, this RfC may overestimate health effects. MADEP recommends using an RfC equal to 0.02 mg/m^3 for C_9 to C_{16} aromatic compounds. MADEP indicated that the NOAEL should not be 900 mg/m^3, rather it should be equal to either 490 mg/m^3 based on reproductive effects reported in a mouse study or 589 mg/m^3 based on developmental effects reported in a rat study. However, in the mouse study, the authors recommended additional studies before any definitive conclusions can be reached about reproductive effects. In the rat study, maternal weight gain was reduced at all exposure levels; thus, conclusions about developmental effects can not be drawn from this study. To conclude

established the USEPA.

that a substance causes developmental effects, maternal health can not be affected because when developmental toxicity is observed only in the presence of maternal toxicity, the developmental effects may not be associated with the substance. Understanding the mechanism of maternal toxicity and the association with developmental effects are required before the relevance of the observations to humans can be addressed (Klaassen, 1996). The MADEP further indicates that while the RfC derived by the TPHCWG may be a representative value for volatile alkyl benzenes, other volatile aromatics with more than one ring in their structure (such as naphthalene) may be present. Thus, they recommend 0.02 mg/m^3 as the RfC for the entire C_9 to C_{16} aromatic fraction. This value incorporates an additional safety factor of 10 for developmental effects and the database deficiency (*i.e.,* including the other compounds such as naphthalene). First, as stated above, conclusions regarding developmental effects cannot be drawn from these studies. Second, although the addition of another safety factor to account for the lack of data for compounds with additional ring structures may be prudent for C_{10} (*i.e.* naphthalene) to C_{16} aromatic compounds, it is likely to overestimate the toxicity of the single ring C_9 to C_{10} aromatic compounds. It should be noted that RfCs developed by USEPA for alkyl benzenes range between 0.1 mg/m^3 and 1.0 mg/m^3. Because naphthalene is the only multi-ring compound in the C_9 to C_{10} aromatic group and because it is analyzed separately as part of the target VOCs and PAHs, the remaining compounds within this group are single ring compounds (*i.e.*, alkyl benzene compounds). Therefore, the toxicity factor used to estimate risks due to exposure to C_9 to C_{10} aromatic compounds were based on isopropyl benzene, which conservatively represents the toxicity of alkyl benzene compounds.

Finally, MADEP has proposed an RfD for aromatic hydrocarbons and alkenes with carbon chain lengths from C_9 to C_{22} using pyrene as the surrogate compound. MADEP assumes appropriately that the RfDs are fairly similar for the polycyclic aromatic hydrocarbons (PAHs) and that one RfD could be used to represent the toxicity of all of these compounds. It is a conservative assumption, however, to assume that the entire aromatic fraction with carbon chain lengths from C_9 to C_{22} consists of PAHs. The scientific literature does not support the hypothesis that the toxicity of the other hydrocarbons containing unsaturated carbon bonds with chain lengths from C_9 to C_{22} (such as the alkylbenzenes, tetralins, benzothiophenes, indens, and alkenes) is the same

as the toxicity of pyrene. In fact, as discussed above, using RfDs for PAHs to represent the toxicity of single aromatic ring compounds such as n-propyl benzene, isopropyl benzene, isopropyl toluene is very conservative. Because the toxic effects and mechanisms of action of most of the aromatic compounds detected in the VPH fraction are more likely to be similar to the alkyl benzene compounds (*i.e.*, single aromatic ring compounds) than PAHs, RfDs consistent with those established for alkyl benzenes ought to be more appropriate. RfDs established for alkyl benzene compounds including toluene, xylenes, ethyl benzene, and n-propyl benzene range between 0.1 mg/kg/d and 2 mg/kg/d. Therefore, the RfD for C_9 to C_{10} aromatic compounds used in this assessment is 0.1 mg/kg/d, which is based on the RfD established for the C_9 aromatic compound isopropyl benzene. Naphthalene, the only polycyclic aromatic compound in this group is considered separately in the target compound list for both VPH and EPH. The RfD for pyrene is used for the remaining C_{11} to C_{22} aromatic compounds.

4.0 EXPOSURE ASSESSMENT

An exposure assessment was performed to identify current or reasonably foreseeable exposure scenarios by which chemicals present at the Site may reach potential human receptors. Potential receptors and exposure pathways were identified, exposure routes were evaluated, exposure point concentrations were estimated, and exposure doses or concentrations were calculated.

4.1 EXPOSURE SCENARIOS

Potential exposure pathways were evaluated for the various media. The following criteria must be met for a complete exposure pathway to exist:

- a source and mechanism to release chemicals into the environment,
- an exposure point at which there is a potential for contact with the contaminated medium by a receptor, and
- an exposure route (*e.g.*, ingestion, inhalation or dermal contact) at the exposure point.

If one of these criteria is not met, then the exposure pathway is not complete. In other words, without any exposure, the risk is zero. Thus, incomplete exposure pathways are eliminated from the assessment. The following sections describe: 1) the soil and ground water categories applicable to the Site; 2) the human receptors likely to be present at this Site; 3) the complete exposure pathways by which the receptors may come into contact with impacted media; and 4) the exposure assumptions used to estimate average daily doses or concentrations.

4.1.1 Identification of Site Soil and Ground water Categories

To evaluate potential exposures to receptors at the Site, the ground water and soil categories are identified. Ground water is categorized by the MADEP based on its current and/or future use as drinking water (GW-1), its potential to act as a source of volatile material to indoor air (GW-2), and its potential to discharge material to surface water (GW-3). The ground water categories applicable to the Site are GW-2 and GW-3. Ground water at the Site is not a potential source of drinking water; therefore, it is not classified as GW-1. Ground water is located less than 15 feet below the ground surface and may be located within 30 feet of a future building. Thus, the Site is considered to be in a GW-2 category. The Site is also considered to be in a GW-3 category because all ground water is assumed to eventually discharge to surface water bodies.

The soil category applicable to the Site under current and future conditions is S-2. The Site is a commercial/industrial property. The majority of impacted soil is located in surface soil. Under current conditions, older children may visit the Site occasionally. However, they are not expected to disturb the soil. Under future conditions, surface soil will be covered either by buildings or asphalt pavement. Adults could be present frequently if they work at the Site and adults and children could visit the Site, however, they are not expected to disturb the soil. If construction work takes place in the future, workers are expected to actively disturb the soil. Excavation activities are, however, not expected to be frequent.

4.1.2 Potential Human Receptors

Under current conditions, this risk assessment considered exposures to:

- Older children who could trespass on the property.

Under foreseeable future conditions, this risk assessment considered exposures to:

- Employees who work at the property;
- Potential future workers who may perform subsurface excavation work during

future construction at the property; and

- Potential future workers who may perform subsurface excavation work while repairing subsurface utilities at the property.

4.1.2.1 Trespassers

Under current conditions, it was assumed that older children could trespass on the property. Exposure routes of concern include incidental ingestion of surface soil, dermal contact with surface soil and inhalation of particulate matter derived from surface soil.

4.1.2.2 Employees

Employees who could work in buildings at a future commercial business could potentially be exposed to VOCs that could volatilize from shallow ground water or soil and migrate into indoor air. However, since VOC concentrations in both ground water and soil were very low (Tables 1 and 4), significant indoor air impacts are unlikely. In addition, surface soil is considered an incomplete pathway because it will be covered either by buildings or asphalt pavement in the future. An Activity and Use Limitation (AUL) with provisions for maintenance of the asphalt pavement and building floor slab will be written to ensure their continued integrity. Therefore, risks to employees were not quantified.

4.1.2.3 Construction and Utility Maintenance Workers

Under future conditions, construction workers could be exposed to impacted surface and subsurface soil and ground water if soil were excavated in the future during construction activities on the property. The principal potential exposure routes include dermal contact with soil, incidental ingestion of soil, and inhalation of particulate matter. Inhalation of VOCs in ambient air during excavation activities was considered but was not evaluated further because wind dispersion and dilution are likely to reduce the concentrations of chemicals in ambient air significantly; thus, it is unlikely that they would pose a significant risk. It should be noted that

VOC concentrations detected in soil and ground water were very low (see Tables 1 and 4); thus, it is unlikely that significant concentrations could be present even in areas without significant dispersion such as a trench. Moreover, the amount of time a worker would spend in a trench over the entire construction period is likely to be limited. In addition, PCBs were not detected in ground water and volatilization from soil to ambient air is likely to be negligible (USEPA, 1996). Skin contact with chemicals detected in shallow ground water is also possible; however, these exposures are not typically quantified because they are usually limited to acute exposures (*e.g.*, incidental splashes on the hands and arms or short-term exposures during the repair of a de-watering pump) (MADEP, 1996). The concentrations of chemicals detected at most disposal sites (including this Site) are not high enough to cause acute health effects via skin contact.

Utility maintenance workers could also be exposed to impacted soil located between the surface and approximately six feet below the surface. The potential exposure routes include dermal contact with soil, incidental ingestion of soil, and inhalation of particulate matter.

4.1.3 Exposure Assumptions

Exposure assumptions for each receptor are described below. Table 7 presents a summary of the assumptions.

4.1.3.1 Trespassers

To estimate exposure doses for older children (age 7 to 18 years old) who may trespass on the former Tombarello & Sons property under current conditions, several assumptions were made. The frequency of exposure was assumed to be 26 days per year, the duration of exposure was assumed to be 4 hours per day and the period of exposure was assumed to be for 12 years. It was assumed that trespassers weigh 46.88 kg, ingest 50 mg of soil per day, and breathe 1.2 m^3 of air per hour (USEPA, 1997a). It was also assumed that trespassers have their forearms, hands, and feet exposed and the weighted soil adherence is equal to 0.14 mg/cm^2 (USEPA, 1992; 1998; MADEP, 2002a). For doses received from inhalation of particulate matter, it was assumed that the Particulate Emission Factor (PEF) was 1.32×10^{-9} and the ventilation rate was equal to 4.8

m^3/day, assuming 4 hours of moderate activity (USEPA, 1996; USEPA, 1997a). The averaging period was equal to the exposure period for exposures to noncarcinogenic chemicals and equal to 75 years for exposures to carcinogenic chemicals (USEPA, 1989; 1997b).

4.1.3.2 Construction Workers

It was assumed that workers involved in construction work would be exposed to impacted soil during excavation activities. Recently, MADEP has published three guidance documents to estimate risks to workers involved in construction activities (MADEP, 2002a,b,c). The first document *Calculation of an Enhanced Soil Ingestion Rate* recommends an ingestion rate for construction workers equal to 100 mg/d (MADEP, 2002b); however, the value recommended by the USEPA (330 mg/day) was used to estimate an ingestion rate at this Site (USEPA, 2002). The second document *Weighted Skin-soil Adherence Factors* is based on a recent review of the literature including recent USEPA information. MADEP developed a skin-soil adherence factor based on data from a study of two groups of utility workers involved in heavy construction work including jack-hammering and excavating trenches with a back hoe and a shovel. The third guidance document *Characterization of Risks Due to Inhalation of Particulates by Construction Workers* accounts for exposure to particulate matter by two pathways including inhalation into the lungs and gastrointestinal absorption following coughing up and subsequent swallowing of the particulates. The assumptions provided in these documents were used to estimate risks to construction workers. A soil ingestion rate of 330 mg/day was used to estimate average daily doses from incidental ingestion of soil (USEPA, 2002). For dermal exposures, it was assumed that the face, forearms, hands, and feet (*i.e.*, 3,477 cm^2) could potentially contact the soil during an exposure event (MADEP, 2002a). A soil adherence factor of 0.29 mg/cm^2 was used to estimate soil adherence during heavy construction work (MADEP, 2002a). It was assumed that the respirable particulate concentration in air (*i.e.*, PM_{10} concentration) was 60$\mu g/m^3$ and that a worker breathes 28.8 m^3/day (60 liters/minute for 8 hours) (MADEP, 2002c). It was also assumed that two-times the PM_{10} would be ingested if inhaled particulates were coughed up and swallowed and that 0.5 times the PM_{10} would enter the lungs (MADEP, 2002c). An average body weight of 71.8 kg was assumed to be the weight of a typical adult (USEPA, 1997a). The

duration of exposure was assumed to be eight hours per day. The frequency of exposure was assumed to be 120 days per year. The exposure period was assumed to be one year. The averaging period was equal to the exposure period for exposures to noncarcinogenic chemicals and equal to 75 years for exposures to carcinogenic chemicals (USEPA, 1989; 1997a).

4.1.3.3 Utility Workers

It was assumed that workers involved in subsurface utility work would be exposed to impacted soil during excavation activities. A soil ingestion rate of 330 mg/day was used to estimate average daily doses from incidental ingestion of soil (USEPA, 2002). For dermal exposures, it was assumed that the face, forearms, hands, and feet (*i.e.*, 3,477 cm^2) could potentially contact the soil during an exposure event (MADEP, 2002a). A soil adherence factor of 0.29 mg/cm^2 was used to estimate soil adherence during heavy construction work (MADEP, 2002a). It was assumed that the respirable particulate concentration in air (*i.e.*, PM_{10} concentration) was 60$\mu g/m^3$ and that a worker breathes 28.8 m^3/day (60 liters/minute for 8 hours) (MADEP, 2002c). It was also assumed that two-times the PM_{10} would be ingested if inhaled particulates were coughed up and swallowed and that 0.5 times the PM_{10} would enter the lungs (MADEP, 2002c). An average body weight of 71.8 kg was assumed to be the weight of a typical adult (USEPA, 1997a). The duration of exposure was assumed to be eight hours per day. The frequency of exposure was assumed to be 5 days per year (MADEP, 1996). The exposure period was assumed to be 25 years. The averaging period was equal to the exposure period for exposures to noncarcinogenic chemicals and equal to 75 years for exposures to carcinogenic chemicals (USEPA, 1989; 1997a).

4.1.3.4 Absorption Factors

It was assumed that 100 percent of the chemical was absorbed from soil by ingestion with the exception of lead. It was assumed that the absorption of lead from soil was equal to 12 percent based on the USEPA default value of 12 percent (USEPA, 2003). Absorption for dermal contact was based on the recommended chemical-specific dermal absorption factors published by

USEPA (1997b). Absorption from inhalation of particulate matter was assumed to be equal to absorption from ingestion because most of the dose received from inhaling particulate matter can be attributed to swallowing material that is coughed up from the lungs (MADEP, 2002c).[6]

4.2 EXPOSURE POINT CONCENTRATIONS

Exposure point concentrations are the estimated concentrations of a chemical in a particular medium at the point of contact. According to USEPA Region I policy, the exposure point concentrations were based on the 95% Upper Confidence Limit (UCL) of the arithmetic mean concentration or the maximum concentration detected (USEPA, 1994).

Table 8 presents the summary statistics for surface soil (zero to one foot below the ground surface) for two "hot spot" areas and for the areas outside the "hot spots". "Hot spots" were considered to be the area around WSB-6 and the area on the southeast corner of the property. Soil between zero and one foot below the ground surface is considered the exposure point for trespassers. Table 9 presents the summary statistics for soil between zero and three feet below the ground surface for three "hot spots" and the area outside the "hot spots". "Hot spots" were considered to be the area around WSB-6, the area in grid quadrant CD-45 and the area on the southeast corner of the property. Soil between zero and three feet below the ground surface is considered to be the primary exposure point for construction and utility workers because the majority of impacts to soil are located at this depth interval. In the tables, the 95% UCL concentrations are shown for some chemicals.[7] UCL concentrations are not shown for chemicals where insufficient data or widely variable data were available because in these cases the UCL concentrations would be greater than the maximum concentrations detected.

Table 10 presents the exposure point concentrations for the trespasser scenario. These concentrations are based on samples collected between zero and one foot below the ground

6 Note that the lifetime carcinogenic dose due to inhalation of cadmium did not consider carcinogenic effects due to swallowing because scientific information indicates that although cadmium may cause lung cancer, the mechanism is likely to be due to a direct effect on the lung.
7 UCL concentrations were based on a lognormal distribution. They were calculated using USEPA equations (USEPA, 1994; Gilbert, 1987.)

surface. The exposure point concentration was assumed to be either the maximum or the 95% UCL of the arithmetic mean concentration, whichever was lower. Likewise, Table 11 shows the exposure point concentrations for the construction worker and utility worker scenarios. Because impacts at this site are primarily limited to surface soils up to three feet below the surface, it was conservatively assumed that excavation work would take place between zero and three feet below the surface. In addition, exposure point concentrations are also presented for soil located between three and 15 feet below the ground surface. These concentrations are based on the maximum concentrations detected in subsurface soil across the Site. It should be noted that the highest PCB concentrations in subsurface soil were detected in the test pits (BRM-TP-4, BRM-TP-5 and BRM-TP9/9A) located in the berm areas along the east and southeast sides of the property. The PCB concentrations ranged between 42 mg/kg and 78 mg/kg in the samples from these test pits. PCB concentrations detected greater than three feet below the surface on other areas of the Site were significantly less.

Two additional discrete areas of contamination were considered for arsenic and cadmium. Arsenic was detected at 69.4 mg/kg in a sample collected between zero and one foot below the surface from boring WSB-10. The next highest concentration detected was 17.9 mg/kg. Because the highest concentration detected was only approximately 4-fold greater than the next highest concentration and because exposure to the area with the highest concentration is not expected to be any greater than any other area, the area in the vicinity of WSB-10 was not considered to be a "hot spot". Thus, the 95% UCL concentration was assumed to be the exposure point concentration for arsenic, which is included in the exposure point concentrations for the area outside the "hot spots" (Table 10). Cadmium was detected at 716 mg/kg in a sample collected between one and two feet below the surface from boring WSB-2. The next highest concentration detected was 12.5 mg/kg., which is greater than 50-fold less than the concentration detected at WSB-2. Because of the significant difference between the concentration detected at WSB-2 and the rest of the Site, this area was considered a "hot spot". Thus, the exposure point concentration was conservatively considered to be 716 mg/kg even though the 95% UCL concentration was 14.1 mg/kg, which is included in the exposure point concentrations for the area outside the "hot spots" (Table 11).

4.3 ESTIMATION OF AVERAGE DAILY EXPOSURES

Equations adapted from USEPA guidance were used to estimate average daily exposure concentrations for inhalation exposures and average daily exposure doses for ingestion of soil dermal contact with soil and inhalation of particulate matter derived from soil (USEPA, 1989). Exposures to chemicals via ingestion and dermal contact are estimated by calculating exposure doses, which are expressed as milligrams of chemical per kilogram of body weight per day. In contrast, exposures to chemicals via inhalation are estimated by calculating average exposure concentrations. Estimating average exposure concentrations rather than average exposure doses is technically more accurate because compounds that elicit route-of-entry effects where the toxic effect is directly on the lung (*e.g.*, irritants and sensitizers) would be inappropriately evaluated if they were calculated as a systemic dose, and pharmacokinetic differences such as absorption and metabolism do not have to be adjusted as would be necessary to estimate a systemic dose. In some cases, toxicity factors are not available to estimate risks from inhalation; in these cases, average daily exposure doses were calculated instead of average daily exposure concentrations.

Estimated average daily exposure doses for incidental ingestion of soil were calculated using the following equation:

$$ADD = \frac{C_x \times IR \times EF \times EP \times C_1}{BW \times AP \times C_2}$$

where:

ADD	=	Chronic or lifetime average daily dose (mg/kg/day)
C_x	=	Exposure point concentration (mg/kg)
IR	=	Ingestion rate (mg/day)
EF	=	Exposure frequency (days/year)
EP	=	Exposure period (years)
C_1	=	Conversion factor (10^{-6} kg/mg)

BW	=	Body weight (kg)
AP	=	Averaging period (years)
C_2	=	Conversion factor (365 days/year)

Estimated average daily exposure doses for dermal contact with soil were calculated using the following equation:

$$ADD = \frac{C_x \, x \, SA \, x \, AF \, x \, ABS \, x \, EF \, x \, EP \, x \, C_1}{BW \, x \, AP \, x \, C_2}$$

where:

ADD	=	Chronic or lifetime average daily dose (mg/kg/day)
C_x	=	Exposure point concentration (mg/kg)
SA	=	Skin surface area in contact with soil (cm^2/day)
AF	=	Soil adherence factor (mg/cm^2)
ABS	=	Absorption factor (unitless)
EF	=	Exposure frequency (days/year)
EP	=	Exposure period (years)
C_1	=	Conversion factor (10^{-6} kg/mg)
BW	=	Body weight (kg)
AP	=	Averaging period (years)
C_2	=	Conversion factor (365 days/year)

For trespassers, estimated average daily exposure doses or concentrations for inhalation of particulate matter were calculated using one of the following equations:

$$ADD = \frac{(\frac{C_x}{PEF}) \, x \, VR \, x \, EF \, x \, EP}{BW \times AP \, x \, C_1}$$

where:

ADD	=	Chronic or Lifetime Average Daily Dose (mg/kg/day)

C_x	=	Exposure point concentration (mg/kg)
PEF	=	Particulate emission factor (m^3/kg)
VR	=	Ventilation Rate (m^3/day)
EF	=	Exposure Frequency (days/year)
EP	=	Exposure period (years)
BW	=	Body weight (kg)
AP	=	Averaging period (years)
C_1	=	Conversion factor (365 days/year)

or:

$$ADE = \frac{(\frac{C_x}{PEF}) \, x \, EF \, x \, ED \, x \, EP \; x \, C_1}{AP \, x \, C_2}$$

where:

ADE	=	Chronic or Lifetime Average Daily Exposure Concentration (mg/m^3 or $\mu g/m^3$)
C_x	=	Exposure point concentration (mg/kg)
PEF	=	Particulate emission factor (m^3/kg)
EF	=	Exposure Frequency (days/year)
ED	=	Exposure duration (hours/day)
EP	=	Exposure period (years)
C_1	=	Conversion factor (days/hour)
C_2	=	Conversion factor (365 days/year)
AP	=	Averaging period (years)

For construction and utility workers, estimated average daily exposure doses or concentrations for inhalation of particulate matter were calculated using one of the following equations:

$$ADD = \frac{C_x \, x \, RP \, x \, VR \, x \, EF \, x \; EP \; x \, C_1}{BW \times AP \, x \, C_2}$$

where:

ADD	=	Chronic or lifetime average daily dose (mg/kg)
C_x	=	Exposure point concentration (mg/kg)
RP	=	Concentration of respirable particulates (mg/m^3)
VR	=	Ventilation rate (m^3/d)
EF	=	Exposure frequency (days/year)
EP	=	Exposure period (years)
C_1	=	Conversion factor (10^{-6} kg/mg)
BW	=	Body weight (kg)
AP	=	Averaging period (years)
C_3	=	Conversion factor (365 days/year)

Or:

$$ADE = \frac{C_x \, x \, RP \, x \, EF \, x \, ED \, x \, EP \; x \, C_1 x \, C_2}{AP \, x \, C_3}$$

where:

ADE	=	Chronic or lifetime average daily exposure concentration (mg/m^3)
C_x	=	Exposure point concentration (mg/kg)
RP	=	Concentration of respirable particulates (mg/m^3)
EF	=	Exposure frequency (d/year)
ED	=	Exposure duration (hours/day)
EP	=	Exposure period (years)
C_1	=	Conversion factor (10^{-6} kg/mg)
C_2	=	Conversion factor (days/hour)
AP	=	Averaging period (years)
C_3	=	Conversion factor (365 days/year)

4.3.1 Trespassers

Trespassers could be exposed to chemicals detected in surface soil on the former Tombarello & Sons property under current conditions. Exposure point concentrations were estimated for areas outside of two "hot spots" using soil samples collected between zero and one foot below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil,

skin contact with soil and inhalation of particulate matter (Tables 12 through 14). Exposure point concentrations were also estimated for the two "hot spot" locations using soil samples collected between zero and one foot below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate matter for the "hot spot" in the vicinity of WSB-6 (Tables 15 through 17) and for the "hot spot" on the southeast corner of the property (Tables 18 through 20).

4.3.2 Construction Workers

Construction workers could be exposed to surface and subsurface soil in the future. Exposure point concentrations were estimated for areas outside of three "hot spots" using soil samples collected between zero and three feet below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil, and inhalation of particulate matter (Tables 21 through 23). Exposure point concentrations were also estimated for the three "hot spot" locations using soil samples collected between zero and three feet below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate matter for the "hot spot" in the vicinity of WSB-6 (Tables 24 through 26), for the "hot spot" in the vicinity of CD-45 (Tables 27 through 29), and for the "hot spot" on the southeast corner of the property (Tables 30 through 32). Exposure point concentrations were also estimated for site-wide deeper soil located between three and 15 feet below the ground surface and average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate matter (Tables 33 through 35).

4.3.3 Utility Workers

Utility workers could be exposed to surface and subsurface soil in the future. Exposure point concentrations were estimated for areas outside of three "hot spots" using soil samples collected between zero and three feet below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate

matter (Tables 36 through 38). Exposure point concentrations were also estimated for the three "hot spot" locations using soil samples collected between zero and three feet below the ground surface. Average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate matter for the "hot spot" in the vicinity of WSB-6 (Tables 39 through 41), for the "hot spot" in the vicinity of CD-45 (Tables 42 through 44), and for the "hot spot" on the southeast corner of the property (Tables 45 through 47). Exposure point concentrations were also estimated for site-wide deeper soil located between three and 15 feet below the ground surface and average daily exposure doses were calculated for incidental ingestion of soil, skin contact with soil and inhalation of particulate matter (Tables 48 through 50).

5.0 RISK EVALUATION

5.1 METHODS TO EVALUATE NONCARCINOGENIC AND CARCINOGENIC RISKS

A risk characterization evaluates current and reasonably foreseeable future health risks associated with site conditions. Risks associated with a site are characterized by integrating data developed in the Hazard Identification, Dose-Response Assessment and Exposure Assessment. Methodologies for evaluating noncarcinogenic health hazards and carcinogenic risks are presented below.

5.1.1 Estimation of Noncarcinogenic Risk

Noncarcinogenic effects are characterized in terms of a Hazard Index. This method assumes that there is an exposure below which adverse effects are not expected to occur (USEPA, 1989). The Hazard Index is calculated for each noncarcinogenic constituent of concern by dividing the average daily exposure concentration (ADE) in mg/m^3 by the chemical-specific reference concentration (RfC), also in mg/m^3, as shown in the equation below.

$$Hazard\ Index = \frac{ADE}{RfC}$$

Or, by dividing the average daily exposure dose (ADD) in mg/kg/day by the chemical-specific Reference Dose (RfD), also in units of mg/kg/day, as shown in the equation below.

$$Hazard\ Index = \frac{ADD}{RfD}$$

The Hazard Indices for each chemical are summed to yield a hazard index for that particular exposure pathway. Then for each receptor, hazard indices for each exposure pathway are summed to yield a total hazard index for the receptor. This hazard index is a screening hazard index. If the screening hazard index exceeds one, then further evaluation is needed to classify chemicals into groups that share similar mechanisms of action. In this case, a separate hazard index is calculated for each group of chemicals that share similar mechanisms of action. If the hazard index for each group does not exceed one, risks associated with exposure to the chemicals are not considered to be significant.

5.1.2 Estimation of Carcinogenic Risk

The potential for carcinogenic health effects is characterized in terms of an incremental lifetime cancer risk, an estimate of the incremental lifetime probability of an individual developing cancer above background cancer incidence. An incremental lifetime carcinogenic risk is calculated for each chemical in the inhalation pathway by multiplying the lifetime average daily exposure (ADE) in $\mu g/m^3$ by the chemical-specific Unit Risk in $(\mu g/m^3)^{-1}$ as shown in the equation below.

$$Risk = ADE \times Unit\ Risk$$

Likewise, the incremental lifetime cancer risk is calculated for each chemical in the ingestion and dermal exposure pathways by multiplying the lifetime average daily dose (ADD) in mg/kg/day by the chemical-specific cancer Slope Factor (SF) as shown in the equation below.

$$Risk = ADD \times SF$$

For each exposure pathway, the chemical-specific risks are summed together, then the risks for each exposure pathway are summed to yield a total risk for that particular medium. Finally, risks for all media of concern are summed to yield a total site risk for each receptor. A total incremental lifetime carcinogenic risk that does not exceed the acceptable total lifetime carcinogenic risk limit indicates that the exposure is unlikely to produce a significant risk of cancer above normal background rates. In accordance with the USEPA, the acceptable lifetime carcinogenic risk limit ranges between 1×10^{-4} and 1×10^{-6} (*i.e.*, one in 10,000 to one in 1,000,000). For purposes of this assessment, it was assumed that the acceptable risk limit was equal to 1×10^{-5} (*i.e.*, one in 100,000) in accordance with the Massachusetts Contingency Plan (1999).

5.2 RISKS TO HUMAN HEALTH

The potential risks to human health were evaluated for each plausible exposure pathway identified in Section 4.0. The intent was to provide reasonable, but conservative, assessment of the degree of risk associated with exposure to the chemicals under current and reasonably foreseeable future conditions.

5.2.1 Trespassers

This assessment assumed that older children could trespass on the former Tombarello & Sons property under current conditions. Tables 51 and 52 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil for areas outside of two "hot spots". Tables 53 and 54 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil for the "hot spot" in the vicinity of WSB-6. Tables 55 and 56 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil and for the "hot spot" on the southeast corner of the property.

The results show that for most of the property both noncarcinogenic and carcinogenic risks are within acceptable limits (Tables 51 and 52).[8] The results also show that direct contact with soil in the "hot spot" area in the vicinity of WSB-6 poses a significant risk of both noncarcinogenic and carcinogenic health effects (Tables 53 and 54). In this area, both the hazard index and incremental lifetime carcinogenic risks are greater than acceptable limits. The unacceptable risk is due to the concentration of PCBs. The results show that risks from direct contact with soil in the "hot spot" area in the southeast area are within acceptable limits (Tables 55 and 56).

5.2.2 Construction Workers

Construction workers may be exposed to soil during excavation activities via incidental ingestion and dermal contact with soil and inhalation of particulate matter. Tables 57 and 58 present the subchronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for areas outside of the "hot spots". Tables 59 and 60 present the subchronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for the "hot spot" in the vicinity of WSB-6. Tables 61 and 62 present the subchronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for the "hot spot" in the vicinity of CD-45. Tables 63 and 64 present the subchronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) and for the "hot spot" on the southeast corner of the property. Tables 65 and 66 present the subchronic hazard indices and incremental lifetime carcinogenic risks for direct contact with site-wide deep soil (3-15' bgs) across the Site.

The results show that for areas outside the "hot spots" noncarcinogenic risks are above acceptable limits. The unacceptable risks are due primarily to PCBs, cadmium and lead. Because the total screening hazard index exceeds one, the hazard indices were evaluated by classifying the chemicals into groups that share similar mechanisms of action. In this case, a separate hazard index is calculated for each group of chemicals that share similar mechanisms of action. The

8 Since both noncancer and cancer risk estimates should be expressed as one significant figure only, the result indicates that this area does not pose a significant risk (MCP, 1999; USEPA, 1989).

bottom part of Table 57 presents the hazard indices for chemicals with similar mechanisms of action. PCBs and PAHs were grouped together because they cause similar noncancer health effects and they both can bind to the Ah receptor, which is the likely mechanism for noncarcinogenic effects. The metals were considered separately because they cause effects by distinct mechanisms. Likewise, petroleum compounds were also grouped together. The bold values in the table show the total hazard index for each group. The results indicate that noncarcinogenic health effects are above acceptable limits only for cadmium. It should be noted that the exposure point concentration for cadmium was based on the high concentration (716 mg/kg) detected in the sample from boring WSB-2. Concentrations of cadmium detected in samples from the remainder of the Site, which are more than 50-fold less than the concentration detected in boring WSB-2, would not pose an unacceptable risk. The results show that for areas outside the "hot spots" carcinogenic risks are within acceptable limits (Table 58).

The results show that direct contact with soil in the "hot spot" area in the vicinity of WSB-6 poses a significant risk of both noncarcinogenic or carcinogenic health effects (Tables 59 and 60). In this area, both the hazard index and incremental lifetime carcinogenic risks are greater than acceptable limits. The unacceptable risk is due to the concentration of PCBs. The results show that direct contact with soil in the "hot spot" area in the vicinity of CD-45 poses a significant risk of both noncarcinogenic or carcinogenic health effects (Tables 61 and 62). In this area, both the sub chronic hazard index and incremental lifetime carcinogenic risks are greater than acceptable limits. The results show that direct contact with soil in the "hot spot" area in the southeast area are within acceptable limits (Tables 63 and 64). The total subchronic hazard index is less than one for workers who could be exposed to surface soil (0-3' bgs) in the southeast area (Table 63). Table 64 shows that carcinogenic risks are also not significant for construction workers who could be exposed to surface soil (0-3' bgs) in the southeast area. It was also assumed that construction work could also take place in deeper soil. The results show that direct contact with deep soil is above the acceptable risk limit for noncarcinogenic effects (Table 65). The unacceptable risk is due to the concentrations of PCBs detected in the berm areas on the east and southeast sides of the property. Carcinogenic risks are within acceptable limits for deep soil (Table 66).

5.2.3 Utility Workers

Utility workers may be exposed to soil during excavation activities via incidental ingestion and dermal contact with soil and inhalation of particulate matter. Risks were calculated for utility maintenance work that could take place on the property in the future. Tables 67 and 68 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for areas outside of the "hot spots". Tables 69 and 70 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for the "hot spot" in the vicinity of WSB-6. Tables 71 and 72 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for the "hot spot" in the vicinity of CD-45. Tables 73 and 74 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with surface soil (0-3' bgs) for the "hot spot" on the southeast corner of the property. Tables 75 and 76 present the chronic hazard indices and incremental lifetime carcinogenic risks for direct contact with deep soil (3-15' bgs) across the Site.

The results show that for areas outside the "hot spots" noncarcinogenic risks and carcinogenic risks are carcinogenic risks are within acceptable limits (Tables 67 and 68). The results also show that direct contact with soil in the "hot spot" area in the vicinity of WSB-6 poses a significant risk of both noncarcinogenic or carcinogenic health effects (Tables 69 and 70). In this area, both the hazard index and incremental lifetime carcinogenic risks are greater than acceptable limits. The unacceptable risk is due to the concentration of PCBs. The results show that direct contact with soil in the "hot spot" area in the vicinity of CD-45 poses a significant risk of both noncarcinogenic or carcinogenic health effects (Tables 71 and 22). In this area, both the hazard index and incremental lifetime carcinogenic risks are greater than acceptable limits due to PCB concentrations. The results show that risks due to direct contact with surface soil in the southeast area are within acceptable limits (Tables 73 and 74). The total chronic hazard index is less than one for workers who could be involved in utility maintenance in the southeast area (Table 73). Table 74 shows that carcinogenic risks are also not significant for workers who

could work in the southeast area. It was also assumed that utility maintenance work could also take place in deeper soil. The results show that direct contact with deep soil does not pose a significant risk to utility maintenance workers (Tables 75 and 76).

6.0 SOURCES OF UNCERTAINTY

Uncertainty is inherent to each stage of the risk characterization process. It is therefore important to identify those uncertainties most critical to the evaluation and to consider their potential impact on the estimation of total site risk because a meaningful risk assessment is a tool for managing anticipated on-site activities. Many kinds of uncertainty enter into the calculation of carcinogenic and noncarcinogenic health risks. Decisions will be made based on a future use scenario, the estimated toxicity of the chemicals of concern, and estimated chemical concentrations in on-site media. Each of these three components is uncertain. First, actual future uses are likely to deviate from current assumptions about who will be on Site, where they will be active, how they will be exposed to the chemical, how long they will be exposed, how repeatedly, and so on. Second, the estimated toxicities are uncertain due to uncertainties in the toxicological data. Third, the chemical concentrations detected in media are uncertain because they are estimated from samples and there are random fluctuations in analytical results due to variations in sampling and analytical procedures. Standard practice in human health risk assessment adopts safety factors to deal with almost every form of uncertainty. The resulting safety factor is so large that levels of risks are certain to be overestimated by orders of magnitude.

A large component of uncertainty arises from the inability to predict future use scenarios. No one can precisely predict the duration or frequency of exposure, the soil ingestion rates, the skin surface area and the body weights of exposed receptors, chemical absorption rates, and the fraction of time spent in the areas of highest chemical concentrations. This creates a level of uncertainty in estimating health risks that can result in either overestimation or underestimation of health risks. One approach to address uncertainty in estimating risks is to use health-protective or conservative assumptions in developing remedial goals. Health-protective assumptions are those that systematically overstate the magnitude of health risks to ensure protection of public health. For example, in this assessment a soil ingestion rate for the

construction and utility worker scenarios was assumed to be 330 mg/day based on the USEPA recommendation. However, the MADEP recommends an ingestion rate equal to 100 mg/d (MADEP, 2002b). Thus, the risks estimated herein for the construction and utility worker scenarios are approximately three fold-higher than would be estimated using MADEP exposure assumptions. Risks due to exposure to PCBs are also likely to be overestimated because the USEPA recommends using an absorption factor for ingestion of soil equal to 100 percent while the MADEP recommends using an absorption factor equal to 85 percent. Likewise, dermal absorption factors for absorption of PCBs from soil are equal to 14 percent using USEPA recommendations while MADEP recommends a factor equal to 6.7 percent. Absorption of PCBs from soil via the gastrointestinal tract and through the skin is likely to be much less than the percentages assumed in this assessment.

Traditionally, the concern with uncertainty in risk assessment procedures stems from exposure assessment methods; however, the uncertainty associated with the exposure parameters seldom spans more than one or two orders of magnitude (10- to 100-fold). In contrast, the assumptions used to evaluate the toxicity of chemicals, rather than exposure, may represent the greatest sources of uncertainty. The potency of a chemical is most often overestimated by several orders of magnitude for noncarcinogenic compounds. In this assessment, noncarcinogenic health effects may be overestimated even more so for metals because subchronic RfDs have not been developed. Therefore, risks to construction workers, who could be exposed for only 120 days (*i.e.*, a subchronic exposure), are evaluated with the same toxicity factor as other receptors, who could be exposed over a working lifetime (*i.e.*, a chronic exposure). Thus, risks to construction workers, who may be exposed on a subchronic basis, are likely to be overestimated. The potency of a chemical is most often overestimated even more for carcinogenic compounds. The extrapolation of cancer potency from laboratory animals to humans, which forms the basis for the cancer risk estimates, may be associated with uncertainties ranging from three to five orders of magnitude (1,000- to 100,000-fold) for selected chemicals. Two general assumptions influence the uncertainty associated with toxicity values developed for chemicals: the assumption that cancer risks are linearly related to exposure (*i.e.*, that carcinogenic effects have no thresholds) and the assumption that exposure variables and toxicity constants formulated for lifetime cancer

risks are applicable for less than lifetime (subchronic) exposures. In addition, it is assumed that values for different chemicals are additive and that values for chemical surrogates are reasonable. To put this more concretely, the step from observing tumors in rats exposed to high doses of PCBs to estimating potential harm to an adult intermittently exposed to parts-per-million levels in soil is a very long one. To ensure human health and safety, standard practice and regulation require that toxicity values reflect "worst-case" results. For most chemicals, actual results — expected ones, in the statistical sense — are likely to result in three to five orders of magnitude less risk than estimates here.

Exposure point concentrations are uncertain because they are based on laboratory analyses of samples or they are based on mathematical models. Exposure point concentrations are dependent on the quality and nature of the sampling data from the site characterization. Sampling bias to areas where higher concentrations are expected or selection of specific analytical methodologies may affect the representativeness of the data. The true concentrations of these samples are probably different from those reported by the laboratory, because analytical results inherently fluctuate randomly about the true concentration. The true values are likely to be within a factor or two of the reported ones. In this assessment, exposure point concentrations were based on maximum concentrations or 95% UCL of the arithmetic mean concentrations according to USEPA guidance. Comparing these concentrations to the average or median concentrations detected on Site (Tables 8 and 9) suggests that the exposure point concentrations used in this assessment are likely to yield very conservative estimates of exposure doses.

In summary, risk is characterized by combining assumptions regarding the level of contamination, the exposure scenario and the toxic potency of the chemical. Since conservative assumptions are used throughout the process, the uncertainties associated with each of these assumptions become multiplicative, which generally results in an overall extremely conservative risk estimate.

7.0 SUMMARY

A Human Health Risk Assessment was performed to evaluate potential risks to human health under current and reasonably foreseeable future conditions. The risk assessment was performed in accordance with the USEPA and MADEP guidance documents. The detailed evaluation of human health risks was divided into four major sections: hazard identification, dose-response assessment, exposure assessment, and risk characterization. Risks were evaluated with respect to exposure to chemicals detected in soil and ground water.

The hazard identification section describes the procedures used to identify chemicals of concern. The Site is impacted primarily with PCBs, PAHs and metals in soil approximately zero to three feet below the ground surface. Ground water impacts are relatively minimal. Low concentrations of VOCs and some metals were detected. It was assumed that VOC concentrations detected in ground water would not result in significant impacts to ambient air or air within buildings that could be constructed. VOCs were also not detected in soil at significant concentrations. Thus, exposure via inhalation of air was not quantified. It was also assumed that future employees who could work at the property would not be exposed to soil because surface soil would be covered either by buildings or pavement. Exposure was quantified for the following scenarios:

- Trespassers, who could be exposed to chemicals detected in surface soil; and
- Construction workers and utility maintenance workers, who may be exposed to impacted soil at the property during excavation activities in the future.

Table 77 presents a summary of the human health risks for trespassers who could be exposed to surface soil at this Site under current conditions. The results indicate that chemicals detected in soil do not pose a significant risk to trespassers with the exception of the "hot spot" area in the vicinity of WSB-6. Table 78 presents a summary of the human health risks for construction workers who could be exposed to soil at this Site. The results indicate that chemicals detected in

soil do not pose a significant risk to construction with the exception of the "hot spots" area in the vicinity of WSB-6, CD-45, the area near WSB-2 (where high concentrations of cadmium were detected), and deeper soil in the berms on the east and southeast sides of the property. Table 79 presents a summary of the human health risks for utility maintenance workers who could be exposed to soil at this Site. The results indicate that chemicals detected in soil do not pose a significant risk to utility workers with the exception of the "hot spots" in the vicinity of WSB-6 and CD-45.

In summary, this risk assessment was performed to evaluate current and reasonably foreseeable future risk to human health. Based on the results of the human health risk assessment, No Significant Risk exists at this Site with the exception of exposure to surface soil in the vicinity of "hotspots" WSB-6, soil between one and two feet below the surface in location CD-45, and deeper soil in the berms located on the east and southeast sides of the Site. In addition, the concentration of cadmium detected in boring WSB-2, which was considered a potential "hot spot", poses a significant risk for construction workers.

8.0 LIMITATIONS

Reasonable care was used in performing all the analyses in this report. The analyses were based on information available at the time of the project and on the assumption that the information provided (such as the sampling and analytical data) is accurate and reliable. The analyses assume that the laboratory analytical data were checked for QA/QC requirements. The analysis assumes that both the source and extent of contamination have been adequately characterized. If additional information becomes available after the completion of this report, if the current or anticipated future uses of the property change after the submission of this report, or if the state and federal agencies change their procedures or their estimates of toxicological properties, then the report will need to be reviewed for appropriateness and accuracy in light of the new information.
